ACKNOWLEDGMENTS

This report was prepared under the general direction of **John F. Long**, Chief of the Population Projections Branch. Statistical assistance was provided by **Thelma C. Hall** and **Pauline B. Shell**. Typing assistance was provided by **Tammy R. Thomas** and **JoAnn E. Fox**. Computer programming was done by **Jerome M. Glynn**, **Leonard Marshall III**, and **Glenn E. Bortz**. Computer graphics assistance was provided by **Maureen P. Lynch**, Statistical Research Division. Publication review assistance was provided by **Rosa B. Taylor**. The report was edited by **Paula Coupe**, Publications Services Division. Overall direction was provided by **Richard Engels**, Assistant Division Chief, Population Division. The assumptions about overall future mortality trends are based largely on the research of **Joseph F. Faber** and **John C. Wilkin**, Office of The Actuary, Social Security Administration. **Signe I. Wetrogan** provided professional consultation and compiled the net immigration statistics, and **John F. Long** provided the confidence interval research. Additional professional consultation was contributed by **Prithwis Das Gupta** and **David B. McMillen**.

Projections of the Population of the United States, by Age, Sex, and Race: 1983 to 2080

INTRODUCTION

This report contains projections of the United States population by age, sex, and race for the years 1983 to 2080. They are based on the July 1, 1982, population estimates and race definitions and are projected forward using the cohort-component method with alternative assumptions for future fertility, mortality, and net immigration levels. These assumptions are shown in table A. The series using the middle assumption for each of the three components is designated as the "middle series." Projections of this series are shown annually by sex and race (White and Black) to 2000, and quinquennially thereafter to 2080. Single year of age information is shown through age 84 and 5-year age groups are provided to age 100 years and over. Five-year age group detail by sex and race is provided for the alternative highest and lowest total population series and the aforementioned years. All other series are shown by 5-year age groups, without sex or race detail, for each future year ending in 0 or 5 to 2030, and selected dates after that time. There are a total of 30 series representing each possible combination of the high, middle, and low assumptions plus three zero migration series.

Table A. Principal Fertility, Mortality, and Net Immigration Assumptions

Subject	Low assumption	Middle assumption	High assumption
Ultimate lifetime births per women.....	1.6	1.9	2.3
Life expectancy at birth in 2080.....	85.9	81.0	77.4
Yearly net immigration, thousands..	250	450	750

Although a preliminary version of these projections was published in October 1982; this is the first detailed report since 1977.¹ In addition to the greater detail, the results of the new projections differ from those of the advance projections for three reasons. First, the begin-

ning point is now the July 1, 1982, population estimates.² Previously we used the estimated July 1, 1981, population.³ Second, the mortality assumptions have been revised to incorporate all the information available through October 1982. Finally, the mortality rates for those aged 95 and over have been modified to reflect recent research by the Office of the Actuary of the Social Security Administration.⁴ The net effect of these changes is very small, except in the 85-and-over age group where the future population is reduced in size.

These projections use the cohort-component method in which the components of population change (births, deaths, and net immigration) are projected separately for each birth cohort (persons born in each year). The July 1, 1982, base population is carried forward year by year using projected survival rates and net immigration by single year of age, sex, and race. Each year a new birth cohort of persons under age 1 is added to the population by applying projected age-race-specific fertility rates to the January 1st female population.

Fertility in the middle series is assumed to reach an ultimate completed cohort fertility of 1.9 births per woman. This is consistent with recent levels of fertility, women's expectations of future births, and social and economic trends leading to lower fertility: increases in labor force participation, educational attainment, and age at first marriage. For the low and high assumptions, levels of 1.6 and 2.3 births per woman are chosen. The ultimate timing pattern of fertility is derived by assuming an ultimate mean age at childbearing of 26.5 in conjunction with slightly modified recent fertility experiences of birth cohorts of White women. These ultimate levels are assumed to be first attained by the 1985 birth cohort for Whites and other races, and by calendar year 2050 for Blacks.

Mortality is projected to decline under all three assumptions. The middle assumption is consistent with projections done by the Social Security Administration in which rapid declines in mortality rates were projected to the year 2005.⁵ After that time, mortality rates decrease more slowly until reaching an ultimate life expectancy of

²Louisa Miller, *Estimates of the Population of the United States, by Age, Sex, and Race: 1980 to 1982*, U.S. Bureau of the Census, Current Population Reports, Series P-25, No. 929 (May 1983).

³U.S. Bureau of the Census, *Preliminary Estimates of the Population of the United States, by Age, Sex, and Race: 1970 to 1981*, Current Population Reports, Series P-25, No. 917 (July 1982).

⁴Joseph F. Faber, *Life Tables for the United States: 1900-2050*, Social Security Administration, Office of the Actuary, Actuarial Study No. 87 (September 1982).

⁵Joseph F. Faber and John C. Wilken, *Social Security Area Population Projections, 1981*, Social Security Administration, Office of the Actuary, Actuarial Study No. 85 (July 1981).

¹U.S. Bureau of the Census, *Projections of the Population of the United States: 1982 to 2050 (Advance Report)*, Current Population Reports, Series P-25, No. 922 (October 1982); and U.S. Bureau of the Census, *Projections of the Population of the United States: 1977 to 2050*, Current Population Reports, Series P-25, No. 704 (July 1977).

81.0 years in 2080. The low mortality assumption projects faster declines in mortality with total life expectancy reaching 85.9 in 2080. Even under the high mortality assumption, life expectancy increases to 77.4 years by 2080. Since declines in the mortality rates for Blacks have historically lagged behind White mortality declines, the life expectancy of Blacks is not projected to reach White levels until 2080 under all assumptions.

The middle assumption for net immigration is a constant annual net inflow of 450,000, roughly equal to the measured level of net annual immigration over the past decade. A wide range between the high and low assumptions of net immigration is needed given our uncertainty as to the future course of refugee movements, possible changes in immigration legislation over the next 100 years, and the lack of adequate data on the legal flows of emigrants from the United States as well as the flows of undocumented aliens into and out of the United States. The high assumption of 750,000 can accommodate most of these concerns. The low assumption of 250,000 assumes little or no undocumented migration to the United States and a substantial outmigration of both aliens and citizens from the United States.

The race definitions used in this report conform with those used in post-1980 census estimates. These differ from the definitions used in the 1980 census. Relative to the census counts, the net effect of the differences is to

increase the White population by 6,438,000, increase the Black population by 135,000, and reduce the population of other races by 6,574,000. A detailed treatment of the modification procedure is available in Current Population Reports, Series P-25, No. 917.

The next two sections concentrate on just 3 of our 30 series. The lowest series assumes low fertility, high mortality, and low net immigration, and the highest series assumes high fertility, low mortality, and high net immigration. These series provide the widest range around the middle series (which was the middle assumption on all components) in terms of future total population size, but do not necessarily represent the extreme range for any particular population subgroup.

PROJECTED POPULATION TRENDS

Population Size and Growth

In the middle series the U.S. population would increase by nearly 80 million persons during the next 100 years; from 232.1 million in 1982 to 310.8 million in 2080 (figure 1, table 2-B). Most of this growth would occur within the next 50 years as the population reaches 268 million in 2000 and 304.8 million in 2030. From 2030 to 2080, the U.S. population would grow by less than 6 million. Even during the 1982-2030 period, population growth in the middle series would be less rapid than it has

FIGURE 1.

Estimates and Projections of Total Population: 1950 to 2080

been in the past (table B). The rate of growth during the 1980's (0.92 percent per year), for example, would be less than in any previous decade except the 1930's (when it was 0.70 percent per year). After 1995, the population grows more slowly than ever before. After 2050, the rate of growth would be virtually zero (0.01 percent per year).

Population growth in the lowest series is naturally much slower (figure 1, table B). By the late 1980's, growth would be less rapid than during the 1930's. Just before 2020 the population would peak at 263 million. The future population would then fall back to its present size by 2050 (232 million), and be further reduced to 191 million by 2080.

In the highest series the United States would experience a very large absolute growth in population, but relatively slow rates of growth. After 2030, the rate of increase would be similar to that of the Depression era (table B). Nevertheless, after 2000, the amount of population growth every decade would be greater than in any previous time (figure 1, table 2-C). The population would be 281.5 million in 2000, 369.8 million in 2030, and 531.2 million in 2080.

Figure 2 presents a disaggregation of the middle series' population growth rate into its component parts. The continual decline in the population growth rate up to 2050 shows up very clearly. It is apparent that the net immigration rate changes very little during the next 100 years. Therefore, the fall in the growth rate is due to a narrowing of the difference between the crude birth and death rates. Up until 2000, most of the convergence in these rates is caused by a decline in the crude birth rate from 16.1 to 13.0 (figure 2, table 2-B). After that time, the crude

death rate rises sharply from 8.8 in 2000 to 12.8 in 2050. This accounts for most of the decline in the growth rate during this period. Shortly after 2030, the crude death rate actually surpasses the crude birth rate, and the rate of natural increase is subsequently negative. The population continues to grow because the rate of net immigration is just sufficient to compensate for the negative rate of natural increase.

Information on the population growth rate and rate of natural increase for the lowest, middle, and highest series is shown in figure 3. The essential trends in the middle series were described in the previous paragraph, but these data are provided here to put the other two series into perspective. It is worth noting that neither rate in the highest series is at all high when compared to the actual post-World War II rates. For the next decade, the population growth rate and the rate of natural increase are above 1982 levels because of higher fertility rates and lower death rates. Most of the decline in the highest series' growth rate after 2000 is due to increases in the death rate resulting from the older age structure (table 2-C). The growth rate is essentially constant after 2030 at levels close to those which existed in the 1930's.

Future trends in these rates are also very interesting in the lowest series (figure 3, table 2-A). Within just a few years the population would be growing more slowly than ever before. The population would actually start to decline by 2020. After 2050 the annual rate of decline is about 6.5 per 1,000 population.

Age Distribution

Median age. One of the most pervasive trends in these projections is the overall aging of the future population. For example, in 1982 the median age of the U.S. population was at an all-time high of 30.6 years (table C). In none of our 30 projection series would the median age ever again be so young. The median age in the middle series would reach 36.3 years at the turn of the century, 40.8 years in 2030, and 42.8 years in 2080. One reason for the dramatic increase in median age over the next couple of decades is evident in the population pyramids for 1982 and 2000 (figure 4). The 1982 population pyramid still impresses one as representing a fairly youthful population; since it is seemingly bottom-heavy. By 2000, however, the massive baby boom cohorts are all over age 35, thus exerting a powerful lifting effect on median age. The baby boom cohorts no longer have such a disproportionate influence by 2030, and the median age rises much more slowly after that time (table C, figure 4). The future median age would always be higher in the lowest series because relatively few young people exist in this population. For the opposite reason, it would always be lower in the highest series. After 2030, the median age in these series would be about 3 years above or below that of the middle series. The median age of the Black-and-other-races population is 25.8 years, almost 5 years below that of the

total population (table C). The gap is about the same for the next 50 years, then begins to narrow as the fertility rates converge. By 2080, the difference is reduced to 1.3 years.

Dependency ratio. The changes in the age structure are also reflected in the dependency ratio. This shows how many children and elderly there would be for every 100 people of working-age, those aged 18 to 64 years (table D). It is likely that the overall ratio of dependents to the working-age population would be lower during most of the next third of a century than at any time since World War II. Further, according to the middle series, at no time during the next century would we see as high a dependency ratio as that which existed in the 1960's. As a matter of fact, the overall dependency ratio until 2020 would be lower than was just the child dependency ratio back in 1965 (65.7).

Through 2010, changes in the overall dependency ratio largely reflect changes in the youthful dependency ratio. After that time it is movement of the elderly dependency ratio that most affects the overall ratio. The dependency ratio of the youthful population would continue to decline from its present level (44.1) to 36.2 in 2010, and then stabilize (table D). During the next 100 years, the youthful dependency ratio would never be as high as it was from World War II until the present. The elderly dependency ratio is now at an all-time high of 18.8. The ratio rises slowly to 21.9 in 2010, and is nearly double its present level by 2030 (37.0). After 2030, the elderly dependency ratio would be larger than the youthful dependency ratio; now it is less than half as large. Similar trends also exist in the highest and lowest series.

Younger ages. The population under age 5 would rise from its 1982 level of 17.4 million to 19.2 million in 1990 in the middle series (table E). Thereafter, it would fall somewhat but stay above the 1982 level until 2070. After 1990, in the highest series this age group would always be larger than ever before. After 1995, the under-5 age group in the lowest series remains smaller than at any time since World War II.

The elementary-school-age population (those aged 5 to 13 years) would decline during the next several years to a point about 0.8 million below the present level of 30.4 million (table E). After that time, it would increase to about 34.7 million persons in the late 1990's, then fluctuate between 32 and 34 million during most of the 21st century. In the highest series, this group would surpass the previous record high in the late 1990's, then continue to grow, reaching double its present size by 2080. In the lowest series, the elementary-school-age population would remain above its 1982 level for most of the next 20 years, then decline steadily.

The high-school-age group, those aged 14 to 17 years, now 15 million strong, would continue to decline to about 13 million in 1990 before beginning to return to a stable level of around 15 million. This group also would decline in the other series during the 1980's because by then these will be the survivors of the baby bust of the 1970's. In the highest series, however, this group would rebound in size and surpass the previous record for this group by 2010 (17.2 million).

The population aged 18 to 24 years, so important to colleges, the military, and employers of new labor force entrants, is now an all-time high 30.4 million (table E). It

would decline more than 7 million during the next 15 years because of the aging of the last of the baby boom generation out of it. In the middle series, this group would rebound to 24.6 million people in 2000 and 27.7 million in 2010. After that time it would fluctuate between these two levels and never again be as large as it is now. This group also would decline in the highest series until the mid-1990's, but then recover quickly enough to exceed the previous record for this group by 2010.

The age groups from 25 to 34 years up through those aged 45 to 64 years all show similar patterns in the future (table E). Each group would first increase as the baby boom generation swells its size, then decline sharply with the subsequent replacement of this group by the

smaller birth cohorts of the 1970's. None subsequently returns to the size it would be when it contains the birth cohorts of 1955 to 1964.

For example, members of the baby boom began to reach age 25 in the early 1970's, and the 25-to-34 age group has been growing rapidly ever since (table E). This age group would not peak in size until 1990 (43.5 million). Within a few years, however, it would have fallen back to its present size (39.5 million), and during the 21st century there would typically be no more than that number of people in this age group. This same pattern would be followed by the older age groups. Only the date of their peak size changes. Those aged 35 to 44 would peak in 2000, those aged 45 to 54 peak in 2010, and so on.

The population of these age groups in the lowest and highest series would also increase and subside in the above pattern (table E). The difference between them is that, in the lowest series, the population of each group would continue to decline after reaching its peak size; while, in the highest series, these groups would surpass their previous baby boom population about 30 years after attaining that size.

The elderly. Another way to examine the aging of the population is to focus on those aged 65 and over (tables E and F). In the middle series, their numbers would steadily increase from the 1982 level of 26.8 million to about 33.9 million in 1995 (table E). Then, because the small birth cohorts of the Depression will be entering their late sixties, the 65-and-over group would grow more slowly, to 36.2 million in 2005. (table 6). Afterwards it would

grow very rapidly to 64.6 million in 2030 as the members of the baby boom reach this age. By 2030, even in the lowest series, the elderly population would be 58.1 million, more than double its present size. In the highest series, the elderly population nearly triples by 2030 (72.6 million), and by 2080 it would be up to 110 million.

The percentage of the entire population that is 65 and older would also grow (table F). Now 11.6 percent, this proportion would reach 13.0 percent in 2000 and 21.2 percent in 2030 in our middle series. After that time, it would slowly rise to 23.5 percent by 2080. Similar changes occur in the lowest and highest series. The highest series, with the most old people, has the lowest percentage of elderly because of the large numbers of younger people in that series. For the opposite reason the lowest series has the highest percent aged.

Source: Derived from table E.

The population aged 85 and over would grow even more rapidly than the 65-and-over group as a whole. This is a result of the assumption that the very old will benefit the most from future mortality improvements. At present, there are some 2.4 million Americans aged 85 and over. Their numbers would double by the start of the 21st century (4.9 million), reach 8.6 million in 2030, and 18.2 million in 2080 (table E). Now about 1 percent of the population is aged 85 years and over (table F). By 2050, 5.2 percent of the population would be that old. Even in the lowest series there would be 6.5 million people aged 85 years and over in 2030, and 10.1 million in 2080. In the highest series, this age group would contain 11.4 million persons in 2030 and 32.5 million in 2080.

The population of those aged 100 years and over also would grow substantially (table E). At present the centenarian population is about 32,000. According to the middle series there would be 108,000 by 2000, 492,000 by 2030, and 1.9 million in 2080. Put another way, now about 30 people a day turn 100. By 2030, 280 would be doing so. In spite of this enormous growth, those aged 100 years and over would probably not be more than 1 percent of the American population in 2080.

Aging of the elderly population. Even as the proportion of the U.S. population which is old increases, the elderly population itself will become older (table G). At present 9.1 percent of those in the 65-and-over age group are aged 85 and above. This percentage would grow steadily to 16.7 in 2010, then drop back to lower levels until after 2030, as the baby boom attains age 65 but not age 85. Afterwards it would climb again to where one-quarter of the elderly are over age 85 in 2080. To one extent or another this phenomenon occurs in all 30 series because of the projected increases in life expectancy.

Race Distribution

Table H shows the future changes in the racial composition of the population according to the middle series. The Black-and-other-races population would continue to grow during the next 100 years from a present level of

33.6 million to 45.3 million in 2000, 63.2 million in 2030, and 79.1 million in 2080. About two-thirds of the growth would occur during the next half century, and the rate of growth thereafter would be slower than at any previous time. In contrast, the White population would increase much more slowly from its existing size of 198.5 million. It would reach 222.7 million in 2000, peak at almost 242 million shortly after 2030, and then decline slowly to 231.6 million in 2080.

In the future the White population never increases more than about 40 percent as rapidly as does the Black-and-other-races population. The effect of this is that the proportion of the population which is Black and other races would continue to rise (table H). It was 10.7 percent in 1950, 12.4 percent in 1970, and 14.5 percent in 1982. The proportion thereafter would increase about 1.3 percentage points a decade. Thus, the percentage of the population that is Black-and-other-races would reach 16.9 in 2000, 20.7 in 2030, and 25.5 in 2080.

Conversely, the fraction of the Black-and-other-races population which is Black would continue to decline. Blacks constituted 89.7 percent of the Black-and-other-races population in 1970 and 82.5 percent of the Black-and-other-races population in 1982 (table 1). That proportion will be down to 78.9 percent in 2000, 75.4 percent in 2030, and 70.4 percent in 2080 (table 6). This occurs despite the fact that Black fertility is assumed to be considerably above that of other races (for further information, see the detailed fertility assumption section). In large part the Black proportion declines because of the relatively high net immigration of races other than White or Black.

In both the highest and lowest series the relative growth of the Black-and-other-races population also would be larger than that of the White population (table 2). The percent Black-and-other-races would be greatest in the highest series because of comparatively higher Black fertility and Black-and-other-races net immigration. It would reach 27 percent in 2080. The proportion Black-and-other-races in the lowest series would be very similar to that of the middle series.

Even if there were no growth because of net immigration, the proportion Black-and-other-races would increase because of higher future Black fertility and the younger age structure of the Black-and-other-races population. In fact, in none of these 30 alternative series would the percentage Black-and-other-races fail to eventually exceed 20 percent.

PROJECTED COMPONENTS OF CHANGE

Total Births

In the middle series, the number of births would remain above the present level of 3.7 million through the early 1990's (table I); even though the peak number of births (3.9 million) actually occurs earlier, in the late 1980's (table 2-B). After the early 1990's, there would never

Table H. Estimates and Projections of the Population, by Race: 1950 to 2080

(Population in thousands. Population as of July 1. Includes Armed Forces overseas. Projection data from middle series)

Source: Derived from tables 1 and 2.

again be more than 3.7 million births because of a decline in the female population of childbearing age. Instead the number of births would fluctuate between 3.4 and 3.7 million. A similar pattern of increased births in the next decade, followed by a decline, also occurs in the highest series (table 2-C). However, in this series, shortly after the beginning of the century there would be more births than even during the baby boom. The annual number of births would subsequently continue to rise, reaching 5.4 million in 2030 and 7.6 million in 2080. In the lowest

series the number of births would always decline, to less than 3 million by 2000, and fewer than 2 million after 2050.

Black-and-Other-Races Fertility

The number of Black-and-other-races births is already at an all-time high of 725,000 (table I). If the middle series proves correct, the number of Black-and-other-races births would increase to almost 900,000 in 2030 and then stabilize. There is not much of a decline in Black-and-other-races births during the 1990's because the number of women of childbearing age continues to increase. In the highest series, Black-and-other-races births rise much more, doubling by 2030 and tripling by 2080. The number of Black-and-other-races births does decline in the lowest series but much less so than do total births.

The proportion of all births that are Black-and-other-races rises somewhat in all series (table I). From the present percentage of almost 20, the proportion in the middle series increases to 22 in 2000, 24.7 in 2030, and 26.6 in 2080.

Women of Childbearing Age

As noted earlier, the total number of births would remain above the present level for the next 10 years (table I). One reason for this, discussed in the next section, would be a rise in the total fertility rate during this period. The other reason would be an increase in the number of women of childbearing age (table J) from 54.6 million in 1982 to a peak of slightly more than 58 million in 1990. After that time the total number of women aged 15 to 44 years would decrease for about 20 years as the aging baby boom cohorts are replaced by the smaller cohorts born during the late 1960's and the 1970's. During the first

part of this period, the total number of births would decline (table I). Black-and-other-races births, however, would not fall very much after 1990, primarily because the number of Black-and-other-races women aged 15 to 44 years is projected to never decline in the future (table J).

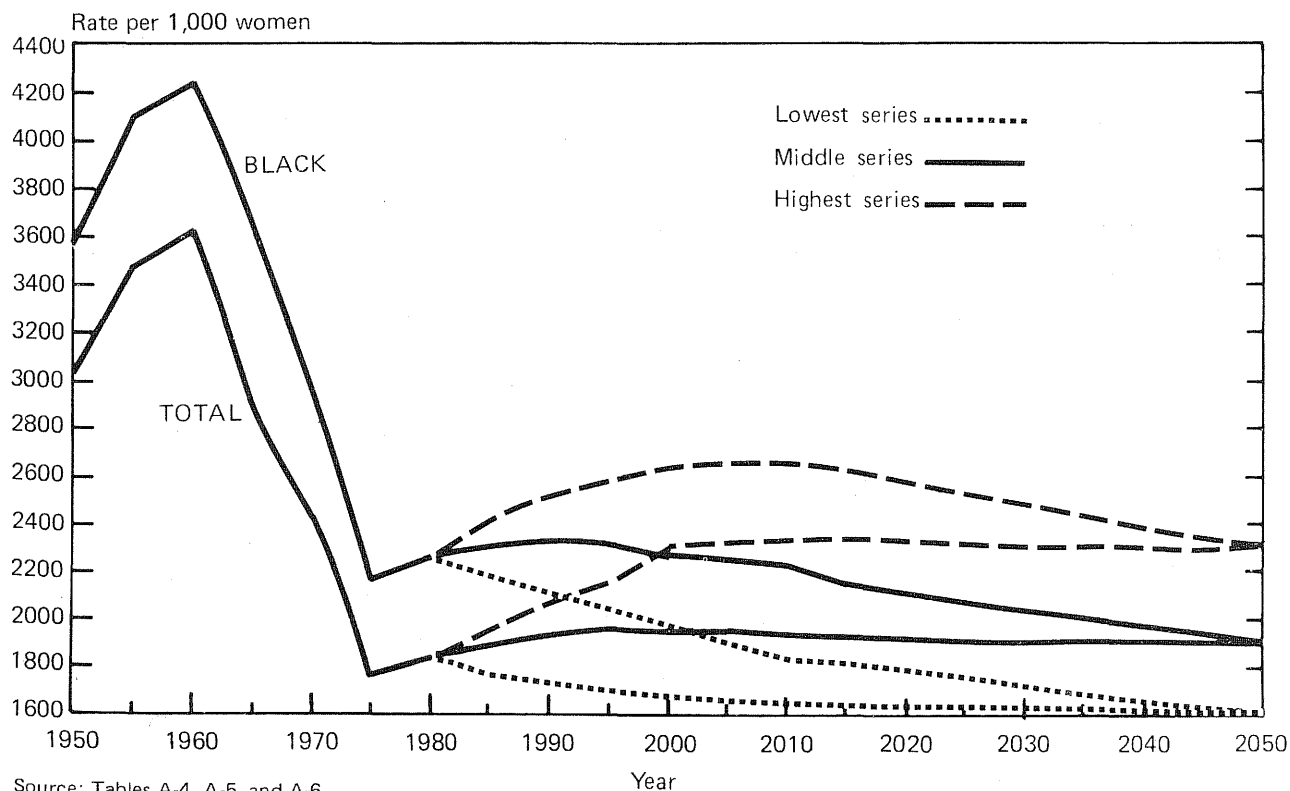

Total Fertility Rate

The total fertility rate indicates the number of children that women would have in their lifetime if, at each year of age, they experienced the age-specific birth rates occurring in a specified year. In the middle series, the total fertility rate rises from a current value of 1,827 births per 1,000 women to about 1,960 births per 1,000 women during the period stretching from 1995 to 2010 (table A-4, figure 5). It then declines slowly to 1,900 births per 1,000 women in 2050 and is constant from then on.

The White total fertility rate, conversely, never gets much above 1,900 births per 1,000 women (table A-5). Instead, it increases from 1,739 now to about 1,900 births per 1,000 women in 2000 and is essentially constant after that. The pattern of change in the Black total fertility rate is very different because of our assumption of racial convergence in fertility by 2050. Now at 2,269 births per 1,000 women, the Black total fertility rate peaks

FIGURE 5.

Estimates and Projections of Annual Total Fertility Rate, by Race: 1950 to 2050

Source: Tables A-4, A-5, and A-6.

early at 2,345 births per 1,000 women in 1990, then begins a slow fall to 1,900 births per 1,000 women in 2050 (table A-6, figure 5). Under the low fertility assumption, the total fertility rate for each group declines steadily to 1,600. In the high fertility series, the overall total fertility rate rises to 2,350 births per 1,000 women about 2015, then falls to 2,300 births per 1,000 women. The White TFR increases to 2,300 births per 1,000 women about 2015 and is then stationary (table A-5).

Young and Old Fertility

One very interesting result of these projections is the fact that, in all series, the fraction of all births occurring to teenagers of any race would never again be as large as it has been in the past decade (table K). In 1975, 19.0 percent of total births and 33.1 percent of Black births were to teenagers. By 1990, however, just 11.8 percent of total births and 19.1 percent of Black births would occur to these young women. The proportion would stay between 11 and 14 percent after that time for the total population. The proportion does not get this low for Blacks until after 2030. Most of the drop from 1975 to 1990 is due to the decline in the proportion of women of child-bearing age who are teenagers.

The opposite trend is found when we examine the percentage of births which will occur among women aged 30 and above (table K). In 1975, such women had 17 percent of total births and 13 percent of Black births. These

2050.....	11.6	27.0	11.9	26.4
2080.....	11.6	26.8	11.8	26.5

¹Black and other races. Percent of Black-and-other-races births under age 20 in 1965 was 23.8. The percent aged 30 and above was 22.8.

Source: Tables A-8 and A-10.

were about the lowest levels in American history. By 1995, though, 30.4 percent of total births and 27 percent of Black births would be to women aged 30 and above. After that time, the proportion for each group would drop down several percentage points and remain at that level, consistent with the long-term historical pattern. This is not to say that the same parity distribution will exist then.

Deaths

The first year in which 2 million Americans died was 1983. From now on it is likely that there would never be a year with less than 2 million deaths (tables L and 2). This is true for all three of our major series. Deaths in the middle series would steadily increase during most of the next century, reaching 2.4 million at the turn of the century and 3.8 million by 2040. After that time, there would be 3.8 to 4.0 million deaths annually. From 2033 to 2080 more deaths than births would occur every year.

Since we have already established that the population is getting older, it is no surprise that the proportion of all deaths which happen at older ages would increase in the future (table L). Currently, about 67 percent of deaths occur at ages 65 and over; that percentage would reach almost 70 by 1985 and would remain over 80 after 2030, reaching 84.6 percent in 2080. More noteworthy is the likely change in the proportion of deaths which happen at ages 85 and over (table L). While 18 percent of all deaths now occur at such old ages; this percentage would reach 30 percent by 2010 and more than 43 percent after 2050.

Net Immigration

A great deal of the interest about future levels of net immigration concerns the impact of net immigration on future U.S. population size. Table M illustrates such an effect for four different levels of net immigration. These series differ only in their migration component as all contain the same middle fertility and middle mortality assumptions.

If there were no net immigration after July 1, 1982, the U.S. population would grow to 258 million people in 2000, peak at 275 million people around 2030 and then proceed to decline to 248 million by 2080. If future net immigration were fairly low (250,000 per year), the population would be 264 million in 2000, level off around 2040 at 294 million, and drop slowly to 286 million in 2080. In comparison with the zero migration series, this population would be 2.1 percent or 5.5 million larger in 2000, 6 percent larger in 2030, 10 percent larger in 2050, and 15 percent larger in 2080. There would be 38 million surviving post-1982 migrants and their descendents in the 2080 population. Net immigration at the middle series level (450,000) leads, as we know from table B, to an essentially zero-growth population after 2050. Therefore, if our middle fertility and mortality assumptions are correct, net immigration much below 450,000 eventually

Table L. Total and Elderly Deaths: 1950 to 2080

(Projected data from middle series. Rounded to hundreds)

Year	Total deaths	Deaths at age 65 and over	Deaths at age 85 and over	Percent of all deaths at age--	
				65 years and over	85 years and over
Estimates:					
1950.....	1,452.5	764.7	116.5	52.7	8.0
1955.....	1,528.7	864.7	145.6	56.5	9.5
1960.....	1,712.0	1,010.0	184.5	59.0	10.8
1965.....	1,828.1	1,110.8	217.1	60.8	11.9

produces a stable or declining population. The middle series population would be 4 percent or nearly 10 million larger than the zero migration series by 2000, 11 percent greater in 2030, and 25 percent or 63 million larger in 2080. The highest net migration series (750,000 a year) grows much more, reaching 274.5 million in 2000, 325

million in 2030, and 355 million in 2080. It would be 16 million or 6.2 percent greater than the zero migration series in 2000, 18 percent or 50 million larger in 2030, and 43 percent larger in 2080. By 2080, there would be 107 million surviving migrants and their descendants in this population.

SELECTION OF ASSUMPTIONS, SENSITIVITY ANALYSIS, AND FORECAST ERROR

Uncertainty of Population Projections and Selection of a Range of Assumptions

The history of population has shown that unforeseen events can rapidly modify the demographic environment. The actual future population is never identical to the projected population. If these projections are to be used as forecasts, then it is important to select alternative assumptions for each of the components so as to provide a reasonable range around the middle assumption.

Although in recent years much attention has been paid to problems of estimating the accuracy of past population projections and the confidence interval of future populations, many problems remain before a reliable confidence interval can be placed around population projections.⁶ There is considerable controversy over the means of handling improvements in methods, changing variability in population growth rates, and other complicating factors. Given these difficulties, the highest and lowest series in this report were not chosen on the basis of a formal analysis of error ranges, but on the basis of the long-standing projections approach of showing a "reasonable high" and a "reasonable low" selected on a judgemental basis.

Past Forecast Error of Population Growth Compared to the Present Range of Assumptions

As an aid to those who would like to attempt a more formal approach to developing a confidence interval around the middle series, we have included information in table N on the root mean square error in past projected rates of population growth versus the actual rates. It is based on all U.S. Bureau of the Census population projections performed in the last 20 years. Comparing the projected growth rate with the actual growth rate and weighting the projection errors equally yields a total root mean square error of 0.33 of a percentage point in projected percent growth. This procedure provides a rather liberal estimate of total error since it weights more heavily the earlier projections (those with the most accumulated actual experience to compare), and those earlier projections were the least accurate of the last two decades. In fact, the last two population projections done in 1975 and 1977 show a root mean square forecast error of the percent growth rate of the total population of only 0.05 of a percentage point. The overall estimate of a root mean square error of 0.33 for the past two decades is in

⁶Michael A. Stoto, *The Accuracy of Population Projections*, International Institute for Applied Systems Analysis, Working Paper 79-75 (1979).

Table N. Root Mean Square Error of Past Projections of the Growth Rate, Compared With Differences Between Selected Series of Present Projections

general agreement with the finding of Nathan Keyfitz of a root mean square error of 0.29 percent in projections for the 30 slowest growing (most developed) countries.⁷ However, unlike Keyfitz, we find that the mean square error in projected growth rates in U.S. projections increases during the first few years of the projection period from only 0.10 of a percentage point for 1 year into the projected period up to 0.32 of a percentage point after 8 years.

Table N compares the differences between the judgementally chosen highest, middle, and lowest series with the calculated root mean square errors for various time spans based on Census Bureau projections made during the last 20 years. If these root mean square errors of previous projections could be taken as estimates of the standard error around the present projections, then there would be roughly a two-thirds chance that a projected growth rate and actual growth rate will be within the range of the root mean square error shown. As the table shows, the present projections do roughly encompass this historical error range for the first 30 years and then appear to widen. After 2030, the difference between the highest and lowest projected series represents a range of plus or minus twice the historical average root mean square error, or roughly a 95 percent confidence interval. Again it should be pointed out that these figures are merely illustrative, and considerable work must still be done before a more reliable method of establishing confidence intervals is available.

Table O shows the joint effects of all these alternative components in the variability between the highest, middle,

and lowest series for 5-year age groups. Results are shown for 1990, 2000, 2025, and 2050. By 1990, differences of greater than 5 percent only exist for the population under age 5 and over 95 while ages between 40 and 79 have differences of less than 1 percent. In 2000, the highest or lowest series differ from the middle series by more than 5 percent at ages under 14 and over 85. By 2025, all age groups show a difference between the extreme and middle projection of over 5 percent, and ages below 30 and over 90 have differences of more than 20 percent. By 2050, only ages between 55 and 84 have differences between the extreme and middle series of less than 20 percent.

Differences in the degree of certainty in the judgemental assumptions for each of the components have differential effects on the projected population age distribution. Differences in the fertility assumptions only affect the size of population age groups born after the beginning of the projection—under 8 by 1990, under 18 by 2000, etc. Differences in mortality assumptions have slight effects on the younger population groups, moderate effects on the middle-aged, and substantial effects on the elderly population. Net immigration has its principal effects first in the young adult age groups and then in older ages as these earlier immigrants age.

Alternative Fertility Assumptions

As in the past several projections, three different future fertility levels are used. In the last two projections the middle series' ultimate fertility level was assumed to be 2,100 births per 1,000 women. This assumption has now been reduced to 1,900. The major reasons for this are as follows:

- 1a. The birth expectations of women aged 18 to 24 years have been well below 2,100 births per 1,000 women since the mid-1970's.⁸ As there are no signs of a rise in these expectations, 2,100 births per 1,000 women would seem to be too high for the foreseeable future.
- 1b. In addition, because single women and childless married women have consistently not attained their birth expectations, these cohorts of young women are very unlikely to even reach their stated birth expectations.⁹ Analysis of these data suggest that none of the cohorts born between 1947 and the mid-1960's are likely to have completed family sizes over 1,900 births per 1,000 women.
- 1c. When the birth expectations information is disaggregated according to the social, economic, and demographic characteristics of women, little is found to indicate that future birth expectations will rise—unless some of the following come to pass:
 - female labor force participation declines
 - female age at first marriage declines
 - more women remain married
 - female educational attainment decreases

Additional information on birth expectations indicates similar patterns.¹⁰

2. For some time, an ever-greater proportion of women have been joining the work force. There is a general consensus that female participation in the labor force is unlikely to decrease and may, in fact, increase.¹¹ Many researchers conclude that fertility consequently will not rise much, if at all.¹²
3. Female age at marriage has been on the rise.¹³ So has the occurrence of divorce.¹⁴ No significant reversal of these patterns seems likely and these factors should continue to depress fertility.
4. Very little of the demographic literature suggests that future fertility will reach 2,100 births per 1,000 women.¹⁵ These opinions have been examined by a number of researchers.¹⁶

The assumed lowest ultimate fertility level is a completed family size of 1,600 births per 1,000 women. This provides a reasonable lower bound for United States fertility, especially given the clear reluctance of women to say they want fewer than two children.¹⁷ This view is supported by the fact that fertility has usually been higher

in the United States than in Western Europe, and even there, only Switzerland and the Federal Republic of Germany have ever been below this level for any period of time.¹⁸ The new highest fertility assumption is 2,300 births per 1,000 women. Given current fertility levels, birth expectations, and most demographic research, this seems to be a plausible high fertility scenario. Nevertheless, it is still much below any of our previous high fertility assumptions. In fact, it is lower than actual U.S. fertility has ever been except for a few years during the Depression and the period since 1972. It is possible that fertility might surpass 2,300 births per 1,000 women, but that does not seem likely given our present knowledge.

The ultimate mean-age-at-childbearing assumption in all series is 26.5 years, up from 26.0 in the last several projections. One reason for this increase is that the period mean age at childbearing is now 25.94 and shows no indication of decline (table A-4). Another is that the cohort mean age at childbearing is on the rise.¹⁹ The median age at marriage is increasing also. Finally, such a change moves this U.S. parameter into better agreement with the typical situation found in Western Europe. That is a reasonable expectation since the United States and Western Europe have become more alike in many other demographic factors.

White-and-other-races women were assumed to reach the ultimate levels of fertility starting with the birth cohort of 1985. Black women do not attain these levels until calendar year 2050. The reason for the delay of the convergence of fertility by race is the clear absence of any such trend, whether measured on a period or a cohort basis (tables A-1, A-2, A-5 and A-6).

Immigrants are assumed to immediately begin bearing children at the same rate as the equivalent age-race group in the United States population. This was deemed necessary in the absence of vital statistics information and because of the many possible changes in the composition of the immigrant population.

One value of creating alternative assumptions for each component is that this enables us to quantify the consequences of variability in a given component more precisely. For example, table P indicates what the future size of the population would be if mortality and net immigration stayed at middle assumption levels and fertility followed our low, middle, or high scenarios. Through the end of the century, it is evident that our range of fertility assumptions do not greatly affect the total size of the population. The alternative series' total populations are only about 2 percent different from the middle series in 2000. The primary reason for this comparatively narrow range is that all variation between the series is necessarily confined to those persons aged 18 years and under in 2000 (those born after July 1, 1982). These young people only

Source: Table 8-B.

would be about 25 percent of the total population then. With the continuing passage of time, however, the range between the fertility series rapidly increases because an ever greater proportion of the population comprises post-1982 birth cohorts. By 2030, the range between the low and high fertility series is 65 million people. The low fertility series' population is 9.7 percent below that of the middle series, and the population of the high fertility series is 11.5 percent above the middle series population (table P). The range increases to 122 million people in 2050 and 229 million in 2080. Fairly small persistent changes in fertility trends obviously may generate huge variations in the future size of the population. A comparison of these results with those to be presented for mortality (table Q), and net immigration (table S) indicates that variation in either of these components has much less effect on population size than do fluctuations in fertility. However, it is important to remember that these fertility differences have no effect on the size of the group born before July 1, 1982; while changes in the other components have some impact on every age group.

Alternative Mortality Assumptions

For the first time alternative mortality assumptions are incorporated in the projections model. The major reason for this change is that, with the stability of fertility rates in recent years, mortality forecast errors have become a significant proportion of the overall error. Mortality accounted for more than 40 percent of the 6-year aggregate error in the last two projections. Another reason is that all Census Bureau projections made in the last 25 years have been too conservative with respect to declines in mortality. Those made since the late 1960's, in fact, have projected at least 8 percent too many deaths by the 6th year of their projection period.

The basis of the alternative series is the projected rates of mortality improvements from a projection prepared by the Office of the Actuary of the Social Security Administration (SSA).²⁰ Because of the rapid improvements in life expectancy since 1968, they also assumed that the rate of improvement from now to 2005 would be much more rapid than after that time. Even so, the actual annual rate of improvement in life expectancy from 1968 to 1982 was much faster than in any of the projected mortality series:

1968- 1982	1982-2005 mortality			2005-2080 mortality		
	High	Middle	Low	High	Middle	Low
0.43	0.08	0.18	0.29	0.03	0.06	0.11

If this past trend did continue the average person born in the middle of the next century could expect to live more than 100 years. It is more likely that these rapid declines are largely due to unique changes in such factors as maternal health care, lifestyle, and the treatment of hypertension; and that these circumstances are not subject to perpetual improvement. An indication of this is the fact that the rate of improvement in life expectancy since 1975 is only two-thirds what it was during the 1968-75 period.

Because the recent trends may not be ignored, however, it seems reasonable to accept the SSA assumption that life expectancy would increase nearly three times as rapidly from now to 2005 as it would after that time. This is a considerable change from our past practice of projecting smooth improvements in mortality between the beginning and ultimate mortality rates.

Life expectancy at birth in the middle series is projected to increase from 74.3 years in 1982 to 76.7 years in 2000 and 81.0 years in 2080 (table B-5). Male life expectancy is assumed to increase from 70.6 years in 1982 to 72.9 years in 2000 and 76.7 years in 2080. Females, who can expect to live 78.1 years under current conditions, are projected to attain a life expectancy of 80.5 years in 2000, and 85.2 years by 2080. Use of the low

²⁰Faber and Wilken, op cit.

mortality assumption generates life expectancies about 2 years higher in 2000 and 5 to 6 years higher in 2080 (table B-5). Life expectancy at birth under the high mortality assumption is a similar amount below the middle series in 2000 and 2080.

Other researchers are unanimous in their agreement that life expectancy will rise.²¹ Many feel it will improve even more than we have assumed, although they seldom forecast beyond 2000. The discussion above, plus the fact that American death rates over age 80 are already the lowest in the world, shows why we believe our assumptions are reasonable.²²

The 1982 mortality data for the White-and-other-races population were combined to produce mortality rates which were then assumed to apply separately to each race. If this procedure had not been followed the life expectancy at birth of the other races population in 1982 would have been 7 years higher than that of Whites. It is our assumption that this disparity is an indication of severe problems in the other races information, rather than representative of any real difference.

Since overall life expectancy is projected to decline substantially in the future, it was not deemed likely that Blacks could attain White mortality levels any sooner than 2080. Even with this postponement of convergence, Black life expectancy at birth improves two to four times more rapidly than White life expectancy (table B-5). There is a good deal of evidence that Black and White differences in life expectancy for women are narrowing more quickly than those for men (table B-5); this is assumed to continue to 2005.

Female life expectancy has been about 7.5 years higher than male life expectancy since 1970 (table B-5). While experts are in disagreement as to whether this differential will narrow or widen, several believe it may narrow by several years.²³ Others believe it may widen to 10 or 12 years by the turn of the century.²⁴ Given this uncertainty as well as the long-term trend toward divergence (table B-5), our assumption is that the sex difference in life expectancy would widen gradually to 8.5 years in 2080.

Immigrants are assumed to be immediately subject to the mortality risks of the appropriate age-sex-race group in

²⁴Crimmins, op. cit.; and Rice, op. cit.

the United States population. This is necessary because of the lack of vital statistics information for immigrants or emigrants.

Life expectancy rises more than 6 years under our middle mortality assumption, reaching 81.0 years in 2080 (table B-5). What would be the effect on the size of the population of an improvement only half as fast or half again more rapid? The short-run effect of these alternative assumptions is minimal (table Q). The range in population size is only 0.7 million by 1990, and 3.1 million in 2000.

These are much smaller variations than those which occur given alternative levels of fertility (table P), or net immigration (table S). In fact, this is the situation at all future dates. Even so, the absolute population range generated by different levels of mortality is considerable: The range between the highest and lowest mortality series reaches 10 million in 2020, 23 million in 2050, and 32 million by 2080. Finally, it is noteworthy that even our most optimistic mortality assumption is not sufficient to prevent the rate of natural increase from being negative after 2041 (table Q).

Table Q. U.S. Population With Different Levels of Mortality: 1990 to 2080

Alternative Net Immigration Assumptions

As with mortality, three alternative net immigration levels are included in the projections model for the first time. One reason for this is that net immigration has recently become a significant component of the overall projection error. Another is that net immigration levels are now higher and, hence, subject to more fluctuation. The effects of proposed Federal legislation on immigration are also unknown. Finally, the high net immigration series is the first-ever attempt to incorporate the net immigration of illegal aliens and higher levels of legal outmigration into the national projections.

Net civilian legal immigration has been higher in the last several years than at any other time since the early 1920's. Monthly data, however, indicate that net civilian legal immigration is declining to a level of about 450,000. This is primarily due to reduced numbers of refugees from Southeast Asia and the cessation of refugee movements from Cuba. Therefore, our middle assumption that annual net immigration will equal 450,000 presumes that there would be no extraordinary inflows of refugees (table R). Because postcensal estimates do not include net illegal immigration, it was also necessary to assume that net illegal immigration is small.

The low net immigration alternative of 250,000 presupposes outmigration to reach an annual level of 160,000 (as compared to 36,000 in the middle series) while immigration drops by about 70,000 from its level in the middle series (table R). This development could occur in several different ways. For example, one might be the combination of poor United States economic conditions and a more restrictive immigration policy.

An annual level of net immigration of 750,000 is the high net immigration assumption. In this series, the net influx of refugees and illegal aliens is assumed to be 424,000 higher than in the middle series. This is toward the high extreme of most estimates of net illegal immigration.²⁵ Outmigration is assumed to be 124,000 higher than in the middle series (because of the increased size of

the foreign born population), which is why the net level is only 300,000 higher than in the middle series.

Table R. Components of Alternative Annual Net Immigration Series

Immigration component	Low	Middle	High
Total net immigration..	250,000	450,000	750,000
Legal immigrants, refugees, Cubans, illegal aliens....	385,000	456,000	880,000
Civilian citizens.....	25,000	25,000	25,000
Puerto Ricans.....	-	5,000	5,000
Outmigrants.....	-160,000	-36,000	-160,000

- Represents zero.

The age-sex-race composition of all immigrants is based on Immigration and Naturalization Service data for the years ending June 30th, 1977, 1978, and 1979. The composition of the outmigration population is based on the existing pattern developed at the Census Bureau for the years from 1960 to 1970.²⁶ The net age-sex-race composition is shown in table C-1.

Our low net immigration assumption is that there would be 2.5 million net migrants per decade added to the population. The middle assumption is 4.5 million net migrants a decade, and the high projection assumes a decadal net immigration of 7.5 million. How much variation in future population size would be produced by this range of net immigration assumptions? By 2000, the range would reach 10 million (table S). It surpasses 30 million by 2030, is almost 50 million by 2050, and nearly 70 million by 2080. Changes in net immigration have a much bigger effect on the population than variations in mortality. One reason is that many additional migrants can produce descendents to add to the future population, while most of those saved from death cannot, as they are too old. Again we note that even high levels of net immigration would not be sufficient to keep the rate of natural increase from eventually becoming negative if fertility stabilizes at 1.9 births per woman.

Making a Choice Among 30 Series

A new complication in these projections is that there now exist 30 alternative series (table T). The middle series, for which the most detail is presented, should suffice for most purposes. However, those interested in a specific population group may now need to pay more attention to alternative series. The major alternative series show the highest and lowest future total population. Other principal alternatives show the effects of independently varying each of the component assumptions (fertility, mortality, and immigration), while leaving the other components at the middle level. These are shown with their descriptive names in table T. Using these series, the effects on future

Source: Table 8.

population size or the age-sex-race composition of a change in just mortality, just fertility, or just immigration can be determined. Also, the possible effect of legislation in such areas as abortion or immigration might be analyzed.

The remaining 20 series in table T represent the other possible combinations of the component assumptions. These series are of less general use, but may be of interest for special analyses. For instance, an analysis of the worst actuarial case for pension plans might use a series with low fertility, high life expectancy, and low net immigration (series 1). The best actuarial case would of course be represented by series 27, which combines the other extremes of the components. Analysts would then have the possible range of eventualities for which their agencies should be prepared.

Similarly, all users of these projections must identify the cost to them of being either too high or too low in projecting the population size or its age-sex-race composition. They can then investigate the possible range in their target population by examination of alternatives to the middle series. If the projections are used with such caution, they can provide a useful tool for long-range planning.

DETAILED METHODOLOGY AND INTRODUCTION TO DETAILED TABLES

The Cohort-Component Accounting Framework

Four sets of data are required to generate these population projections using the cohort-component model. These are a base-year population, projected fertility rates, projected survival rates, and future net immigration statistics. The procedures by which these data are generated by single year of age, sex, and race are described in the sections which follow.

Once these data have been produced it is a relatively straightforward process to apply the cohort-component model and produce projections. The first step is to organize the July 1, 1982, base population into six matrices with a cell for each year of age from 0 to 100 and over. The six matrices are the White, Black, and other races population by sex. The next step is to survive each age-sex-race group forward to July 1, 1983, using the pertinent survival rate. The appropriate number of net immigrants are then added to each group, under the simplifying assumption that all immigrants survive to the projected date. These two simple steps are all that were needed to generate a July 1, 1983, population projection by sex, race, and single years of age from 1 to 100 and over.

The population under age 1 is then created by first averaging the July 1, 1982, and July 1, 1983, female population of each race by single years of age from 14 through 49. This yields an approximation of the female population exposed to the possibility of childbearing during that period. The appropriate age-race-specific fertility rate for that period was then applied to the female population to produce, after aggregation, the total number of births by race from July 1, 1982, to July 1, 1983. The assumed future race-specific sex ratio at birth was then used to divide the births into males and females. Finally, the number of births by sex and race were survived forward to give us the population under age 1 on July 1, 1983. The same set of procedures, when applied to the July 1, 1983, population, would generate the July 1, 1984, population projection. The process is continued until 2080.

It is important to note that the inflation-deflation variant of the cohort-component method used in the previous set of national projections is not used here because of the unavailability of final adjustment factors for net undercount in the 1980 census. This means that birth cohorts can now be followed as they age. Unfortunately, the patterns of change in age groups across time are inaccurate for those persons in the July 1, 1982, base population. The reason is that the undercount varies by age. Table F-1, while not ideal for this purpose, probably does provide a reasonable picture of the degree to which the undercount does differ from age to age. Groups undercounted relative to younger groups will exhibit spuri-

... Not a principal series.

ously rapid growth rates in the future. Age groups which were overcounted in comparison to younger groups will show too slow a future growth. As an example, the Black group aged 85 and over will show faster growth in the coming decades than is correct. Black males aged 70 to 74, conversely, will exhibit slower growth than is truly happening.

Such problems would be avoided if these projections could be based on a population adjusted for net census undercount. This procedure is not used because:

1. The available estimates of net census undercount do not make any allowance for the substantial number of illegal aliens included in the census count. Even if accurate estimates of the number of such illegal aliens by age, sex, and race existed, we would still need to know many additional illegal aliens were not counted in the 1980 census.
2. Estimates of net census undercount are subject to error and revision.
3. They are not available for subnational areas.
4. They are not compatible with existing time series.
5. It is not possible to ascribe many social and economic characteristics to the unenumerated population.

Estimation of the Base Population

The beginning population of these projections is the July 1, 1982, population estimate (table 5).²⁷ The only differences from the published data are the use of unrounded estimates and single year of age data up to 100 years and over. Users of these projections should realize that the base-year estimates were largely developed from provisional fertility, mortality, and net immigration information. Since they are subject to subsequent revision, a potential source of error in these projections is any change in the base population.

More importantly, these estimates and projections often cannot be compared directly to the 1980 census results because two adjustments were made to the census. First, the post-censal race definitions are inconsistent with those of the 1980 census. They are consistent with Office of Management and Budget Directive 15 and with vital statistics procedures beginning in 1978. The overall net effect was to increase the White population by 6,438,225 and the Black population by 135,493. The other-races population decreased by 6,573,718. These changes are preliminary and are subject to further revision.

The other change in the 1980 census was to modify the population counts for each single year of age over 75.

²⁷Miller, op cit.

This was done to adjust for age misreporting as well as for the edit procedure used to allocate persons to the 100 and over age category. This change indicates the uncertainty which still exists about the accuracy of the data base for these older groups. This uncertainty is not terribly important in these projections because the projected older population soon will largely be the survivors of present-day younger, more accurately enumerated groups.

Fertility Methodology

In order to utilize the cohort-component method, fertility data were required through 1982. Final information is available prior to 1980 from the National Center for Health Statistics (NCHS).²⁸ It publishes birth data by single year of age and race (White, Black and other races, Black) which have been adjusted for underregistration. The 1980 statistics which NCHS also provided us were not adjusted for underregistration. Subsequent information through June, 1982, was only for the provisional number of total births.²⁹

Population data. Prior to 1980 the population base used to calculate birth rates was the resident female population by single year of age and race (White, Black-and-other-races, Black) adjusted for underenumeration in the censuses through 1970.³⁰ The 1980 and 1981 population estimates of resident females are consistent with the results of the 1980 census, but are not adjusted for underenumeration as the Bureau of the Census has not yet produced final undercount factors. The 1982 estimates of the female population were from an unpublished set of national projections which were based on preliminary July 1980 estimates derived from the 1980 census.

Birth rate data. The central birth rates developed by NCHS for White females by single year of age were used for all years prior to 1980. Because of a lack of data prior to 1964, the NCHS fertility statistics for Blacks-and-other-races were assumed to apply to Blacks. From 1964 to 1979, we have generated Black fertility rates from unpublished NCHS information.

Creation of 1980-82 central birth rates. The 1980 rates for Whites and Blacks were produced in the following way. First, the registered level final NCHS births for 1980 were inflated by the single year of age and race underregistration factors from the 1979 NCHS data. Second, unrounded resident female population estimates by race were produced for each age X using the $0.125 \cdot (\text{population aged } X-1) + 0.75 \cdot (\text{Population aged } X) + 0.125 \cdot (\text{population aged } X+1)$ formulation to approximate the population aged X in 1980 likely to experience a birth at age X in 1980. Third, White and Black birth rates were then produced by simple division after which they were smoothed by use of a 3 years of age moving average with both 13 and 50 set equal to 0.

The population base for the 1981 fertility rates were constructed in the same way. Births by age and sex were generated by first inflating the provisional registered total number of births by the overall 1979 underregistration factors from NCHS. This yielded an estimate of 3,672,685 births in 1981. Then estimates of births by single year of age and race were produced by multiplying the 1981 population estimates by the previously constructed 1980 age-race-specific rates. Because of deficiencies in the available data, the number of other races births was estimated by applying the White birth rates for 1980 to the appropriate 1981 population estimate. The aggregate number of births produced in this way was 3,641,467. The number of births in each age-race group was then inflated by the ratio of 3,672,685 to 3,641,467. The White and Black birth rates were then generated in the same manner as described earlier for 1980.

The 1982 population base by age, sex, and race from the unpublished projections was adjusted in the same way as were the 1980 and 1981 figures. Provisional total birth data were only available through June 1982. A projection of 3,666,000 births for the year was derived from an analysis of recent monthly birth statistics.³¹ From this point on, the same procedures were followed as described above for 1981. This completed the creation of the historical fertility series. The 1982 fertility schedule is shown in table U.

Ultimate fertility rates. The first step in producing projected fertility rates was to generate a set of ultimate level age-specific birth rates which were consistent with the assumed mean childbearing age of 26.5 and assumed ultimate fertility levels of 1,600, 1,900, and 2,300 births per 1,000 women. This was accomplished by projecting past changes in the shape of White birth cohort fertility schedules until a middle series schedule was obtained which fit the above parameters (table U). During this process, the fertility of those under age 18 was not allowed

³¹Shortly after the fertility projections were completed, NCHS revised the provisional number of births for the first 6 months of 1982 upwards by 14,000. If we had been able to incorporate this information, our projected number of births for 1982 would have been higher by 29,000. However, the adjustment for underregistration increases the number of births by approximately 27,000. Therefore, during the first part of the projection, our forecast number of births is more similar to the registered number of births than to the true number.

Table U. White Birth Rates, by Single Year of Age for Calendar Year 1982, and the 1959 and 1985 Birth Cohorts

to rise above their 1982 levels. The high and low model fertility schedules were then derived by application of the ratio of the alternative completed family sizes to that of the middle series to each age-specific birth rate in the middle series.

Projected middle series White fertility schedule. A middle fertility series for White females was then constructed from 1982 to the first ultimate fertility level birth cohort, those born in 1985. A crucial decision was to focus on completing the fertility schedule of those White females aged 20 to 24 in 1981. These represent the largest birth cohorts ever born in the United States and we felt it important that their future fertility be modeled as intensively as possible. In 1981, this group expected

to finish their childbearing with 2,025.9 children per 1,000 women.³² This was reduced to 1,879.7 on the basis of recent work by O'Connell and Rogers which found that the accuracy of birth expectations is very dependent on the marital status of respondents.³³ They discovered that those who are ever married or who marry within 5 years seem to predict their future fertility quite well. The remaining initial respondents revise their birth expectations sharply downward after 5 years. Only 57.8 percent of those aged 20 to 24 were ever married in 1981. According to the 1976 to 1981 data, just half of the remaining 42.2 percent will be married within 5 years and achieve their birth expectations. Adjusting the birth expectations of the remaining 21.1 percent produced the figure of 1,879.7 births per 1,000 women. Recent evidence has shown that such a use of birth expectations data is a fairly good predictor of the aggregate number of births to cohorts already in the childbearing years.³⁴

This adjusted figure was assumed to apply to the 1959 birth cohort, the middle of the 1957 to 1961 cohorts. The remainder of the age-specific fertility schedule of this cohort was completed by first modifying the results of the slope analysis conducted to produce the ultimate fertility schedule in order to yield factors relevant to the 1959 cohort. These factors were then applied to the remaining childbearing years of the 1959 cohort (ages 24 and above) to generate a fertility schedule which added to their modified birth expectation (table U). This also resulted in the 1959 cohort having the highest mean age at childbearing of any cohort now of childbearing age, as well as all future cohorts. This delay in childbearing accords with the idea that these women may be the most demographically disadvantaged of all the baby boom cohorts.³⁵

Age-specific White cohort fertility rates for the pre-1959 birth cohorts still of childbearing age were obtained by linear interpolation between calendar year 1982 and the previously constructed 1959 birth cohort rates. The future fertility of cohorts born between 1959 and 1985 was then obtained by linear age-specific interpolation between these two cohorts. Neither set of interpolated results were modified in any way. Therefore, some oscillations appear in the completed fertility of cohorts now of childbearing age. At this point, a complete middle series of White fertility rates had been created.

Projected low and high White fertility schedules. The high and low future fertility rates for Whites were then produced. First, a linear interpolation from calendar year 1982 to the 1985 birth cohort was made for all three ultimate fertility levels. In other words, three naive projections were made without taking the above modifications into account. Second, in order to expand the short-term fertility range, the series' differences from the naive middle

³²Unpublished data from the June 1981 Current Population Survey.

³³O'Connell and Rogers, op. cit.

³⁴John F. Long and Signe I. Wetrogan, "The Utility of Birth Expectations in Population Projections," Hendershot and Placek, op. cit., pp. 29-50.

³⁵Easterlin, op. cit.

series which would have existed in 1983 if the interpolation had begun in 1979 were assumed to exist in 1983. Finally, the single year of age differences between the alternative interpolation series and the interpolated middle series were applied to the original middle series, thereby yielding the alternative fertility series for Whites.

Projected Black-and-other-races fertility. Black fertility rates were then derived by the following procedure. The ratio of Black-to-White central birth rates by single years of age was calculated from the 1980 data. These ratios were then assumed to apply to 1982. Each ratio was assumed to equal zero in 2050. Linear interpolation was used to obtain intermediate-year ratios for each single year of age. Lastly, at each future time the appropriate ratios were applied to the three series of White fertility rates. Because of deficiencies in the available data, those who are neither White nor Black were assumed to have White fertility levels in all future years.

Sex ratio at birth. The final step was to generate the sex of the births. The sex ratio at birth in each year after 1979 was assumed to be constant for each race. It was computed separately for White, Blacks, and other races as an average of the NCHS data for 1975 to 1979.³⁶

Mortality Methodology

The 1982 lifetable. The 1982 lifetable is based on final NCHS data for 1979 and subsequent 10-percent sample information by age, sex, and race through October 1982.³⁷ The number of Black and Black-and-other-races deaths by sex for age groups 0-1, 1-4, 5-9, 10-14, . . . , 90-4, 95+ were developed for the year ending June 30, 1982. This was accomplished by disaggregating the 10-percent sample data using the detailed 1979 data. Deaths by sex and race for those aged 70 and over were adjusted to the age pattern of deaths occurring in the 1980 Medicare population.³⁸ Statistics for the White Medicare population were used to modify aged White-and-other-races mortality and those for Black and other races served as adjustment factors for Black deaths. The number of deaths in every group for the year ending June 30, 1982, was then adjusted to accord with an estimated 1,987,000 deaths in calendar year 1982. The mortality rates by sex and race for those under age 95 were computed using the July 1, 1982, population estimates.³⁹ Mortality rates by sex for those aged 95 to 120 were adapted from a set of factors based on a 1981 life table recently prepared by

the Office of the Actuary of the Social Security Administration.⁴⁰ The identical pattern of increased mortality with increased age was assumed to be applicable to both the very old Blacks and the very old White-and-other-races, although the levels of mortality were different. It is important to note that this same procedure was used to calculate those death rates over age 95 in all future years.

The 2005 lifetables. These base-year data were combined with projected rates of improvements from projections prepared by the Office of the Actuary of the Social Security Administration to yield three alternative mortality schedules by age, sex, and race for 2005 and 2080.⁴¹ The percentage improvements in future mortality rates in their middle series is based on an analysis of past and prospective mortality trends by age, sex, and cause of death. Like theirs, our high mortality series is based on the assumption that the percentage improvements in mortality will be half as rapid as in their middle series. Our low mortality series is quite different from that done by the Social Security Administration (SSA). Ours was derived from a set of percentage improvements in mortality rates only 50 percent more rapid than those of the middle series, while theirs is based on 100 percent more rapid improvements in mortality rates.

The percentage improvement by sex from 1980 to 2005 for each age group through 80-84 years was calculated from the middle series of SSA rates for those dates. These were adjusted to apply to the 1982 to 2005 period, then used in conjunction with our 1982 death rates to create age-sex mortality rates for 2005 which were consistent with the results of the 1980 census. Age-specific rates of improvement over age 85 were not available in the 1981 SSA projections. For those aged 85 to 94 years these rates were derived by use of projected rates of improvement for the 1981 to 2006 period recently published by SSA.⁴² Percentage improvements for the 1982 to 2005 period were created from these data and applied to our 1982 rates for those aged 85 to 94. The high and low mortality series for 2005 were produced using the previously described assumption that the percentage improvements for ages 0 to 94 were half as fast or 50 percent more rapid than those produced for the middle series. These rates of improvement were then applied to our 1982 mortality rates to create the alternative mortality schedules. The rates for ages 95 to 120 in these series were derived in the same manner as described earlier for 1982.

These three series of projected age-sex mortality rates were then modified to include race detail since the SSA projections were not done by race. As mentioned earlier, mortality differentials between Blacks and those of another race have been diminishing more rapidly for females.

⁴²Faber, op cit.

This was assumed to continue until 2005 when the present racial difference for women was assumed to have been narrowed by one-third while that for men would have decreased by one-quarter. The population weights used to disaggregate the overall mortality rates in 2005 for those under age 85 were unpublished data for the population by age, sex, and race in 2005.⁴³ The weights used for those aged 85 to 94 are from the same source, but for the year 2000 as those projections did not show such detail past 2000.

2080 lifetables. A middle series of age and sex mortality rates for those under age 85 in 2080 were obtained in a manner similar to that outlined for the creation of the 2005 death rates. That is, the rates of improvement between 2005 and 2080 in the 1981 SSA projections were combined with our 2005 mortality rates to yield new rates for 2080. For those aged 85 to 94, these rates of change were obtained by assuming that projected changes during the 2006 to 2056 period that were recently published by SSA would continue to operate during the entire 2005 to 2080 period.⁴⁴ These percentage improvements were then applied to the 2005 rates for those aged 85-94 to yield projected rates for 2080. By 2080, there is assumed to be no racial difference in mortality and hence there was no need to decompose the overall rate.

All the mortality rates thus produced for 1982, 2005, and 2080 were then used to generate life tables by single years of age, sex, and race from which survival rates were subsequently calculated. Finally, survival rates for the intermediate years from 1982 to 2005 and from 2005 to 2080 were obtained by geometric interpolation.

Net Immigration Methodology

The only remaining task, after the creation of an assumed total for each migration component (table R), was to distribute these totals by age, sex, and race. For legal aliens, civilian citizens, and Cubans, we used the appropriate average age-sex-race distribution found in Immigration and Naturalization Service (INS) data for the July 1, 1976, to July 1, 1979, period. Since refugees could come from any area, it did not seem appropriate to use the INS refugee statistics. Instead, the refugee population was distributed on the basis of the INS legal alien information. Puerto Rican migrants were distributed according to an age-sex-race pattern developed in the Census Bureau. For illegal aliens, the INS data for legal aliens was utilized. For all the above components, the same relative distribution was used, no matter what the assumed level of the component was. For emigrants, however, a different distribution was used for each level of outmigration. Both distributions were developed in the State and National Estimates Branch of the Census Bureau.

Construction of Special Populations

The projections in this report all pertain solely to the total future United States population including Armed Forces overseas. Appendix tables D-1 and E-1 provide users with the information necessary for the derivation of several special populations. The specific derivation procedures are described below.

Resident population. This is obtained by subtraction of the Armed Forces overseas population (table D-1) from the appropriate projection series in tables 6 to 10.

Resident civilian population. Subtraction of the entire Armed Forces population (table D-1) from the relevant projection series in tables 6 to 10 will yield this population.

Resident civilian noninstitutional population. Application of the ratios in table E-1 to the pertinent projection series (tables 6 to 10) generates the noninstitutional population. Subtraction of the Armed Forces population then produces this population.

Availability of More Detailed Data

For each of the 30 series, the basic product of our methodology is a set of unrounded population counts by single years of age, sex, and race, for each year from 1983 to 2080. Fertility, mortality, and net immigration statistics were also produced with the same degree of detail. Most of these data are not published, but all of them are available from the Bureau of the Census, either in hard copy or in machine-readable form. Further information may be obtained by writing to the Chief, Population Division, Bureau of the Census, Washington, D.C. 20233.

SUMMARY AND CONCLUSIONS

These national projections show what the future population by age, sex, and race will be given various assumptions about fertility, mortality, and net immigration trends. Three different assumptions were made about the possible course of each of the components of population change. The 27 combinations of these assumptions plus three zero net immigration series all portray a future American population which will grow relatively slowly, if at all. Additionally, the population is likely to be much older and contain more minorities. There is a strong likelihood that there will always be more deaths than at present. Conversely, we may never have many more births than now occur. No previous report has presented so much age or race detail. For the first time, analysts also can measure the effects on future population change or composition of a change in fertility, mortality, or net immigration.

¹Source: Current Population Reports, Series P-25, Nos. 310, 802, 917, 929, and 939.

²The information for the total population is from Current Population Reports, Series P-25, Nos. 802 and 939. The statistics by race prior to 1960 were developed by averaging the July 1 figures in Current Population Reports, Series P-25, No. 310; then adjusting these to fit to the total population figures in Current Population Reports, Series P-25, No. 802. The statistics by race for the 1960's are from Current Population Reports, Series P-25, No. 802. The more recent estimates were derived by averaging the July 1 numbers in Current Population Reports, Series P-25, Nos. 917 and 929, then adjusting these to be consistent with the data in Current Population Reports, Series P-25, No. 939, and an unpublished estimate for January 1, 1983.

³Includes estimates of overseas admissions into and discharges from the Armed Forces and the error of closure between censuses. For further information, see Current Population Reports, Series P-25, Nos. 802 and 917.

⁴Adjusted for underregistration. The 1950 to 1969 births were adjusted according to the results of the 1950 Birth Registration Test. For further information, see Appendix tables A-8 to A-10.

⁵Deaths occurring in the United States plus estimated deaths occurring to Armed Forces overseas. Infant deaths adjusted for underregistration through March 1960.

⁶The racial components of change in these years are from unpublished Census Bureau estimates.

Table 2. Total Population—Annual Projections and Components of Change, for the United States:

1983 to 2080

¹A birth cohort is defined as those women born in the 12-month period centered on the beginning of the year in question. (For example, the 1910 cohort comprises females born July 1, 1909, to June 30, 1910.)

Table A-2. Black Females—Estimates and Projections of Cumulative Fertility, by Age: Selected Birth Cohorts, 1910 to 2040

(Rates represent live births per 1,000 women up to age indicated. See text for discussion of methodology and assumptions)

Series and birth cohort of women ¹	Cumulative fertility rates ²						Completed cohort fertility rate	Mean age of childbearing	Median age of childbearing
	Up to age 20	Up to age 25	Up to age 30	Up to age 35	Up to age 40	Up to age 45

^aEstimates of total fertility rates differ slightly from those published by the National Center for Health Statistics. The estimates in this report are the sum of central birth rates which are based on births adjusted for underregistration and females adjusted for estimated net census undercount. The total fertility rates published annually by the National Center for Health Statistics are the sum of age-specific birth rates. The estimates of total fertility rates and central birth rates in this report through 1973 are also published in Robert L. Heuser, *Fertility Tables for Birth Cohorts by Color: United States, 1917-1973*, DHEW Publication No. (HRA) 76-1152, U.S. Government Printing Office, 1976.

Table A-5. White Females—Estimates and Projections of Total Fertility Rates and Fertility Rates, by Age: Selected Years, 1940 to 2025

(Rates represent live births per 1,000 women. See text for discussion of methodology and assumptions)

Series and calendar year	Total fertility rate ¹	Central birth rates								Mean age of childbearing	Median age of childbearing

¹Estimates of total fertility rates differ slightly from those published by the National Center for Health Statistics. The estimates in this report are the sum of central birth rates which are based on births adjusted for underregistration and females adjusted for estimated net census undercount. The total fertility rates published annually by the National Center for Health Statistics are the sum of age-specific birth rates. The estimates of total fertility rates and central birth rates in this report through 1973 are also published in Robert L. Heuser, *Fertility Tables for Birth Cohorts by Color: United States, 1917-1973*, DHEW Publication No. (HRA) 76-1152, U.S. Government Printing Office, 1976.

Table A-6. Black Females—Estimates and Projections of Total Fertility Rates and Fertility Rates, by Age: Selected Years, 1940 to 2050

(Rates represent live births per 1,000 women. See text for discussion of methodology and assumptions)

Series and calendar year	Total fertility rate ¹	Central births rates								Mean age of childbearing	Median age of childbearing
		10 to 14 years	15 to 19 years	20 to 24 years	25 to 29 years	30 to 34 years	35 to 39 years	40 to 44 years	45 to 49 years

¹Estimates of total fertility rates differ slightly from those published by the National Center for Health Statistics because births are adjusted for underregistration and the female population is adjusted for net census undercount prior to 1980.

²Prior to 1964, data are not available for Black females. Estimates are for females of Black and other races of whom 92 to 98 percent were Black in each 5-year age group in the 10 to 49 age span in each census from 1920 to 1960. For comparative purposes, data for both Black and Nonwhite females are shown for 1965.

Table A-7. Estimates and Projections of General Fertility Rates, by Race: 1940 to 2080

(Rates per 1,000 women 15 to 44 years of age)

Calendar year	Lowest series (series 19)			Middle series (series 14)			Highest series (series 9)		
	Total	White	Black	Total	White	Black ¹	Total	White	Black
Estimates:

¹The information prior to 1965 is for the Nonwhite population. In 1965 the Nonwhite general fertility rate was 127.3.

Note: General fertility rates based on births shown in tables A-8 to A-10. Prior to 1980 the population base is the midyear corrected resident female population consistent with Current Population Reports, Series P-25, Nos. 311, 519, and 870. Alaska and Hawaii are not included prior to 1960. The 1980 to 1982 population base is the midyear census-level resident female population consistent with Current Population Reports, Series P-25, No. 929.

Table A-8. Estimates and Projections of Total Births, by Age of Mother: 1940 to 2080

(Numbers in thousands. Births adjusted for underregistration in all years)

¹Total births used as input to the fertility projections of this report were based on earlier estimates of 3,677.5 million births in 1981 and 3,692.8 million births in 1982. See text for further information.

Note: The 1940 to 1980 information is unpublished final NCHS data consistent with the central birth rates published in the annual NCHS volume on natality. The 1981 and 1982 statistics were estimated from provisional total registered births from NCHS, the single year of age corrected and registered births for 1980 from NCHS, and single year of age estimates from Current Population Reports, Series P-25, No. 929. Alaska and Hawaii are not included prior to 1960. The numbers of births shown here during the 1950's and 1960's were adjusted to reflect the results of the 1964 to 1968 birth registration test. For further information, see: Robert L. Heuser, *Fertility Tables for Birth Cohorts by Color: United States, 1917-73*, DHEW Publication No. (HRA) 76-1152, 1976.

¹White births used as input to the fertility projections of this report were based on earlier estimates of 2,931.3 million White births in 1981 and 2,970.2 million in 1982. See text for further information.

Note: The 1940 to 1980 information is unpublished final NCHS data consistent with the central birth rates published in the annual NCHS volume on natality. The 1981 and 1982 statistics were estimated from provisional total registered births from NCHS, the single year of age corrected and registered births for 1980 from NCHS, and single year of age estimates from Current Population Reports, Series P-25, No. 929. Alaska and Hawaii are not included prior to 1960. The numbers of births shown here during the 1950's and 1960's were adjusted to reflect the results of the 1964 to 1968 birth registration test. For further information, see Robert L. Heuser, Fertility Tables for Birth Cohorts by Color: United States, 1917-73, DHEW Publication No. (HRA) 76-1152, 1976.

Table A-10. Estimates and Projections of Black Births, by Age of Mother: 1940 to 2080

(Numbers in thousands. Births adjusted for underregistration in all years)

¹Black births used as input to the fertility projections of this report were based on earlier estimates of 631.0 thousand Black births in 1981 and 620.0 thousand in 1982. See text for further information.

Note: The Nonwhite information for 1940 to 1965 is final unpublished NCHS data consistent with the central birth rates published in the annual NCHS volume on natality. The Black information for 1965 to 1980 was estimated by inflating the registered Black birth data from NCHS by the appropriate under-registration factor for the total Nonwhite population. The 1981 and 1982 statistics were estimated from provisional total registered births from NCHS, the single year of age corrected and registered births for 1980 from NCHS, and single year of age estimates from Current Population Reports, Series P-25, No. 929. Alaska and Hawaii are not included prior to 1960. The numbers of births shown here during the 1950's and 1960's were adjusted to reflect the results of the 1964 to 1968 birth registration test. For further information see: Robert L. Heuser, *Fertility Tables for Birth Cohorts by Color: United States, 1917-73*, DHEW Publication No. (HRA) 76-1152, 1976.

Appendix B. Mortality

**Table B-1A. Five-Year Survival Rates, by Age and Sex, for the Total Population, 1982 to 2080:
Low Mortality Assumption**

(Census survival rates are based on projections of population in 5 year age groups assuming no net immigration. These rates reflect survival rates by single year of age and the age distribution within each age group. See text for discussion of methodology and assumptions)

**Table B-1B. Five-Year Survival Rates, by Age and Sex, for the White Population, 1982 to 2080:
Low Mortality Assumption**

(Census survival rates are based on projections of population in 5 year age groups assuming no net immigration. These rates reflect survival rates by single year of age and the age distribution within each age group. See text for discussion of methodology and assumptions)

Initial age	Terminal age	Census survival rates								Life table survival rates		
		1985 to 1990	1990 to 1995	1995 to 2000	2000 to 2005	2005 to 2010	2010 to 2015	2015 to 2020	2020 to 2025	1982	2005	2080

**Table B-1C. Five-Year Survival Rates, by Age and Sex, for the Black Population, 1982 to 2080:
Low Mortality Assumption**

(Census survival rates are based on projections of population in 5 year age groups assuming no net immigration. These rates reflect survival rates by single year of age and the age distribution within each age group. See text for discussion of methodology and assumptions)

Initial age	Terminal age	Census survival rates								Life table survival rates		
		1985 to 1990	1990 to 1995	1995 to 2000	2000 to 2005	2005 to 2010	2010 to 2015	2015 to 2020	2020 to 2025	1982	2005	2080

Table B-2A. Five-Year Survival Rates, by Age and Sex, for the Total Population, 1982 to 2080: Middle Mortality Assumption

(Census survival rates are based on projections of population in 5 year age groups assuming no net immigration. These rates reflect survival rates by single year of age and the age distribution within each age group. See text for discussion of methodology and assumptions)

Initial age	Terminal age	Census survival rates								Life table survival rates

Table B-3A. Five-Year Survival Rates, by Age and Sex, for the Total Population, 1982 to 2080: High Mortality Assumption

(Census survival rates are based on projections of population in 5 year age groups assuming no net immigration. These rates reflect survival rates by single year of age and the age distribution within each age group. See text for discussion of methodology and assumptions)

Initial age	Terminal age	Census survival rates								Life table survival rates		
		1985 to 1990	1990 to 1995	1995 to 2000	2000 to 2005	2005 to 2010	2010 to 2015	2015 to 2020	2020 to 2025	1982	2005	2080

**Table B-3B. Five-Year Survival Rates, by Age and Sex, for the White Population, 1982 to 2080:
High Mortality Assumption**

(Census survival rates are based on projections of population in 5 year age groups assuming no net immigration. These rates reflect survival rates by single year of age and the age distribution within each age group. See text for discussion of methodology and assumptions)

Initial age	Terminal age	Census survival rates								Life table survival rates		
		1985 to 1990	1990 to 1995	1995 to 2000	2000 to 2005	2005 to 2010	2010 to 2015	2015 to 2020	2020 to 2025	1982	2005	2080

Table B-3C. Five-Year Survival Rates, by Age and Sex, for the Black Population, 1982 to 2080: High Mortality Assumption

(Census survival rates are based on projections of population in 5 year age groups assuming no net immigration. These rates reflect survival rates by single year of age and the age distribution within each age group. See text for discussion of methodology and assumptions)

Initial age	Terminal age	Census survival rates								Life table survival rates

Table B-4E. One-Year Life Table Survival Rates and Life Expectancies, by Sex: 2080—Continued

(See text for discussion of methodology, assumptions, and meaning of symbols)

Initial age	Terminal age	2080 survival rates for all races						2080 life expectancy at initial age for all races					
		Low mortality		Middle mortality		High mortality		Low mortality		Middle mortality		High mortality	
		Male	Female	Male	Female	Male	Female	Male	Female	Male	Female	Male	Female

¹Nonwhite.

²Life expectancy at birth was 61.0 for nonwhite males and 69.0 for nonwhite females. At age 65 the respective values were 12.9 and 16.0.

³Unpublished information from the National Center for Health Statistics revised to incorporate new population estimates consistent with the 1980 census.

⁴Provisional. See text for discussion of methodology and assumptions.
