Projections of the Hispanic Population of the United States: 1983 to 2080

HIGHLIGHTS

The national projections in this report show what the future Spanish-origin population would be under various assumptions about fertility, mortality, and net immigration trends. Three different assumptions were made about the possible future course of each of these components of population change. Review of the assumptions yields the conclusion that these projections may be somewhat conservative with respect to the future size of the Spanish-origin population. Here are some of the highlights of this report:

- The Hispanic population may double within 30 years and triple in 60.
- Most of the growth of the Spanish-origin population would occur among those aged 35 and older.
- The Spanish-origin population aged 65 years and older may quadruple by 2015 and be seven times its present size in 2030.
- Even without international migration, the Spanish-origin population may grow more quickly than would most other major population groups with immigration.
- The White non-Hispanic population may peak in size by 2020, and then steadily decrease.
- The White non-Hispanic proportion of the total population may decline in the future.

INTRODUCTION

This report contains the first projections produced by the Federal Government of the Spanish-origin population by age, sex, and race for the years 1983 to 2080. The assumptions and methodology used in these projections are consistent with those of the latest national projections.¹ These projections are based on July 1, 1982, population estimates and race definitions and are projected forward using the cohort-component method with alternative assumptions for future fertility, mortality, and net immigration. The ultimate levels assumed for these Spanish-origin components are identical to those of the race groups in the national projections (table A). Details of

¹U.S. Bureau of the Census, Current Population Reports, Series P-25, No. 952, *Projections of the Population of the United States, by Age, Sex, and Race: 1983 to 2080*, (May 1984). However, these projections are not consistent with the monthly Current Population Survey figures for the Spanish-origin population. One reason is that these projections began on July 1, 1982, and were not adjusted to reflect more recent information. Second, at the time these projections were prepared, the Census Bureau did not include undocumented immigration in postcensal population estimates and projections because of problems in measuring this component.

Table A. Hispanic Fertility, Mortality, and Net Immigration: 1982 and Assumed Ultimate Levels

Subject	1982	Low assumption	Middle assumption	High assumption
Total fertility rate.....	2.7	1.6	1.9	2.3
Life expectancy at birth.....	75.5	77.4	81.0	85.9
Yearly net immigration (thousands).....	191.9	85.7	143.2	361.5

the assumptions and methods used in this report are presented in later sections of this text.

The series using the middle assumption for each of the three components is designated the "middle" series. Population projections for this series (as well as the alternative highest and lowest total population series) are shown annually by age and sex to 2000, and for selected dates after that time. Information is shown by single year of age through age 44 and for 5-year age groups to age 85 years and over. Information for alternative net immigration series, alternative fertility series, and alternative mortality series are shown for 5-year age groups, without sex detail, for each future year ending in 0 or 5 to 2030, and for selected dates after that time. The same degree of detail is provided for the White Hispanic population in all the aforementioned series. Although statistics from other series are not included in this publication, there are data available for a total of 30 different series, representing each possible combination of the high, middle, and low assumptions plus three zero-migration series. Information about how to obtain more detail for any of the 30 series is included at the end of this text.

Users of these projections should realize that the actual future population is never identical with any projected population. All users should identify the cost to them of being either too high or too low in projecting the population size or its composition. They can then investigate the range in their target population group by examination of alternatives to the middle series. If the projections are used with such caution, they can provide a useful tool for long-range planning.

These projections of the Spanish-origin population, an ethnic group, were done by race of the Spanish origin so they would be consistent with our national projections (which are done by race). Although the focus of this report is the Spanish-origin population, a portion of the text is devoted to the presentation of information from the national projections for

the total population and several race/ethnic groups. This information provides users with a contextual setting for the Spanish-origin projections. This is necessary because future national projections will include the Spanish origin as a separate group. That later section also gives users of these projections some previously unpublished information for Blacks, White non-Hispanics, and other races.

PROJECTED HISPANIC POPULATION TRENDS

This section presents information on the lowest, middle, and highest projection series for the Spanish-origin population. The lowest series assumes low fertility, high mortality, and low net immigration, and the highest series assumes high fertility, low mortality, and high net immigration. These series provide the widest range around the middle series (which is the middle assumption on all components) in terms of future total population size, but do not necessarily represent the extreme range for any particular population subgroup.

Population size and rate of growth. The Spanish-origin population is increasing rapidly. A continuation of that growth is projected to occur throughout the projection period (table B). However, the rate at which the Hispanic population would grow is projected to decline (table C).

In 1982 there were 15.8 million Hispanics in the United States.² In the middle series, that number of Hispanics would be added to the U.S. population approximately every 30 years (table B). The Hispanic population would be 31 million in 2010, 47 million in 2040, and 60 million in 2080. Between 1982 and 2000 alone, the Hispanic population would increase 9 million or 60 percent. The annual rate of growth of this population was about 3 percent in 1982. It would decline to 2 percent shortly after 2000, and to less than 1 percent a year by 2040 (table 1-b).

The growth of the Spanish-origin population would be more spectacular if the highest series were to prove correct (tables

²The terms "Spanish origin" and "Hispanic" are used interchangeably in this report.

Table B. Hispanic Population: 1982 to 2080

(As of July 1. Numbers in millions. Includes Armed Forces overseas)

Year	Lowest series	Middle series	Highest series

2070 to 2080	-0.2	0.4	1.1

Source: Derived from table 1.

B and C). Shortly after 2000 there would be twice as many Hispanics as there are now, and the Spanish-origin population would be growing by one million persons per year. In the highest series, the Spanish-origin population would be four times its present size in 2030 (68 million), and nine times its present size in 2080 (141 million). Even in the lowest series the Hispanic population would still double by 2030 (table B). The Spanish-origin group will constitute a significant portion of the future American population, regardless of the assumptions made about its demographic behavior.

Median age. One of the most pervasive future trends described in the national population projections was the almost inevitable overall aging of the population (table R). Several aspects of this trend are now examined for the Spanish-origin population. As first illustrated by the median age data in table D, this movement toward an older population structure would also occur among the Spanish-origin population. This

Table D. Median Age of the Hispanic Population: 1982 to 2080

(As of July 1. Includes Armed Forces overseas)

Year	Lowest series	Middle series	Highest series
1982	24.1	24.1	24.1
1985	25.1	25.0	24.7
1990	26.6	26.3	25.4
1995	27.9	27.2	25.9
2000	29.1	28.0	26.2
2010	31.3	29.3	26.7
2020	33.9	31.2	27.7
2030	36.3	33.0	28.8
2050	39.9	36.2	31.6
2080	44.3	40.9	35.9

Source: Tables 2, 3, and 4; and unpublished data.

occurrence is primarily the result of the assumption that Hispanic fertility would decline steadily after 1990 (table J). The median age of Hispanics was 24.1 years in 1982. In none of the 30 different projection series would their median age ever again be so low. The median age of the Hispanic population would reach 28.0 years in 2000, 33.0 in 2030, 36.2 in 2050, and 40.9 in 2080. The future median age of the Spanish-origin population would always be higher in the

lowest series because comparatively few young people exist in this population (where future fertility is assumed to be low). For the opposite reason, the median age of Hispanics would always be lower in the highest series than in the middle series.

Dependency ratios. One important societal issue which is affected by such significant changes in an age structure is the relationship of the number of non-workers in the Nation to the number of workers.³ The ratio of the number of non-workers to the number of workers is called the "dependency ratio." Although there are many complicated factors to be considered, in general a low or falling dependency ratio is viewed as a favorable circumstance. The data in table E do not perfectly measure this phenomena because they compare those

Table E. Number of Dependents per 100 Persons Aged 18 to 64 Years, for the Hispanic Population: 1982 to 2080

Source: Table F.

of working-age (defined as those 18 to 64 years) with those who are younger or older. The correct comparison would be workers of whatever age contrasted with all those who are not working. However, the use of age groups is an adequate approximation. It is also important to look at both age components of the ratio, the youthful dependency ratio (those under age 18), and the elderly dependency ratio (those aged 65 and older).

³Preston, Samuel H., "Children and the Elderly: Divergent Paths For America's Dependents," *Demography*, Vol. 21, No. 4, (November 1984), pp. 435-457.

In 1982, the Spanish-origin overall dependency ratio was 72. In the middle series, the Hispanic ratio would not be this high again during the next 100 years, although it never would be much lower either. The overall dependency ratio of Hispanics in the lowest series usually would be a bit lower than in the middle series. The opposite is true of the highest series. This seeming constancy conceals massive changes in the composition of the dependent population. In the middle series, about 9 of 10 Hispanic dependents now are youngsters. That proportion would decline to 7 of 10 in 2030 and 5 of 10 in 2080 (table E). The extent of this change in composition would be greater in the lowest series and less in the highest series.

The fall in the share of all Hispanic dependents who are youngsters is a consequence of the assumption that Hispanic fertility, even in the highest series, will be lower in the future (table J). As shown in table E, for example, in all three series the Spanish-origin youthful dependency ratios never again would be as large as they are now (aside from minor exceptions in the highest series).

The elderly dependency ratio is the portion of the overall dependency ratio which usually is paid the most attention—primarily because this group receives direct income transfers from the working-age population. According to the middle series, the elderly dependency ratio of the Hispanic population would steadily increase during the next century (table E). The Spanish-origin elderly dependency ratio would double within 40 years and quadruple by 2080. The increases in the ratio are especially noteworthy after 2010. Similar trends also exist in the lowest and highest series.

Population size by age group. In the middle series, all the Spanish-origin groups under age 18 would follow similar growth patterns (tables F and G). Each would be about 50 percent larger by 2000 and twice their present size by 2030. In spite of such growth, these youthful groups all would be increasing less quickly than the total Hispanic population. For example, about 37 percent of the Spanish-origin population now is under age 18 (table G). Even after doubling by 2030, this group then would constitute only 28 percent of all Hispanics. In the middle series, those under 18 would represent only 21 percent of the Spanish-origin population by 2080 (even though each age group would continue to increase from 2030 to 2080). This relative diminution is a direct result of the assumption that the future fertility of the Spanish-origin population would be considerably lower than it is now.

The combination of an absolute increase in the future number of young Hispanics with a concomitant decrease in their proportion of the future total Hispanic population is also seen in the lowest and highest series (tables F and G). Naturally, these young age groups would grow less rapidly in the lowest series because fertility is projected to be so low in that series. Even so, around 2020 the number of Hispanics under age 18 would be a third larger than in 1982 (table F). During the next several decades, then, it seems likely that the number of Hispanic youngsters would remain above its current level. It is also true, however, that these young people

are likely to make up a smaller fraction of the future Hispanic population. This is demonstrated by the projection information for the highest series (tables F and G). The Hispanic population under age 18 in the highest series would double by 2000 and quadruple by 2030. Nevertheless, their share of the total Spanish-origin population in 2030 would be down to 33 percent (from 37 percent in 1982).

Similar trends occur among the Hispanic groups aged 18 to 34 years. However, these groups would grow more slowly than the younger age groups. The 18 to 24 portion of that population would only be 18 percent larger in 2000, while there would be 32 percent more Hispanics aged 25 to 34 years in 2000 than there are now. The cause of this slow growth is illustrated in figure 1 where the 0-to-14 age groups in 1982 (approximately 18 to 34 in 2000) are seen to be little different in size from the 18-to-34 age group in 1982. As was true for those under age 18, the Spanish-origin population aged 18 to 34 in the middle series would go on to double by 2030—then grow comparatively slowly. Their percentage of the Spanish-origin population would fall from 33 percent in 1982 to 26 percent in 2000, 25 percent in 2030, and 21 percent in 2080. To a greater or lesser degree, similar trends for 18-to-34 year-olds would occur in the lowest and highest series.

In summary, future Hispanic groups under age 35 would contain more people, but represent a lesser share of the total

Hispanic population. For example, in the middle series this group under age 35 would grow from 11 million persons in 1982 to 15 million in 2000 and 22 million in 2030. Yet their percentage of the total Spanish-origin population would drop from 70 percent in 1982 to 61 percent in 2000 and 53 percent in 2030.

Hispanic population growth would be much more rapid among the groups over age 35 (tables F and G). In the middle series, the 35-to-44 age group would double by 2000, triple by 2030, and quadruple by 2080. As rapid as this growth may seem, it pales in comparison with that of any older age group. For instance, those aged 45 to 64 will quadruple by 2030 (half the time it would take the 35-to-44 age group), and be seven times their current size in 2080. The number aged 65 years or more would quadruple by 2015, be seven times their existing size in 2030 (half the time it would take the 45 to 64 group), and there would be 16 times as many Hispanics aged 65 years and over in 2080 as in 1982. The growth of the Spanish-origin population aged 85 years and older is even more rapid than the growth of the 65 and over age group (tables F and G). There were approximately 54,000 Hispanics aged 85 years and older in 1982. This group would double in the next decade and quadruple within a quarter-century. There would be 12 times more Hispanics aged 85 years and older in 2030 than there were in 1982, 30 times as many in 2050, and, finally, 50 times as many in 2080. It is hardly

Source: Table F.

necessary to note that all these groups over age 35 would represent larger proportions of the future Hispanic population.

Projected components of population change. Throughout this analysis attention has been paid to the rapid growth of the Hispanic population. The growth of this group is the joint product of the effects of fertility, mortality, and net immigration on the population age structure. In this section, these joint effects are presented separately to allow individual analysis of each component. Neither the independent effect of age structure differentials nor the interactive relationships among fertility, mortality, and net immigration can be elucidated from these comparisons. For instance, immigration has some effect on both the fertility and mortality of a population. Its exact impact cannot be calculated from these data, but it is not large. The rate of occurrence of each component per 1,000 total Hispanic population is shown in table H.

Most Spanish-origin population growth is attributable to natural increase (birth rate minus death rate). In the middle series this relationship would be maintained through the year 2050. This would happen even though each component of Hispanic population change constantly would move toward a lower growth level. The essential finding here is that, even without further immigration, the Spanish-origin population in the middle series would continue to grow for quite a long time. This is important because it contradicts the impression that

Hispanic population growth is primarily due to immigration. The same results are found in the data from the lowest and highest series (table H).

Births. The number of Spanish-origin births would rise considerably in the future if the middle series proves to be correct (table I). In 1982, there were about 400,000 Hispanic births. By 2000, there would be over 500,000, and in 2030, there would be about 660,000. After that time the number of births would stabilize as the growth of the childbearing-age population slows and Hispanic fertility begins to approach the ultimate level (table J). In the lowest series, the number of Hispanic births still would manage to remain above the current level until after 2030. That would happen because numerical increases in the Hispanic population of potential mothers would be sufficient until then to compensate for the rapid fall in their fertility rates (table J). Given these results, it is fairly obvious that the number of Hispanic births in the highest series would grow dramatically (table I). Their numbers would double by early next century, triple by 2030, and quadruple by 2050. From table J, we see that such increases in the number of births would occur with only minor increases in fertility rates.

Deaths. In all three series there would be an increased number of deaths among the Spanish-origin population during each

Source: Table 1.

of the next 100 years (table K). This would happen in spite of assumed mortality improvements (table B-4). The reason is that the Spanish-origin population would become both much larger and considerably older (tables B and D). There are now about 70,000 Hispanic deaths a year. In the middle series that number would be 116,000 in 2000 and 159,000 in 2010 (more than double the present number of deaths). There would be four times as many deaths in 2030 (294,000) as there are now and nine times the current number by 2080 (table K). The total number of Hispanic deaths in the lowest and highest series would be nearly identical with those in the middle series through 2020. This would happen because the lowest population series incorporates the highest death rates while the highest population series includes the lowest future death rates. After 2020, this compensating factor is overwhelmed by the sheer difference in population size of the alternative series.

Net immigration. Net immigration of the Spanish-origin population earlier was shown to be an important component of this group's rapid future increase. However, according to these pro-

jections, it would not be as important as would be the anticipated excess of births over deaths (table H). One reason for this is that net immigration is represented by a constant absolute number of people in these projections and not by some rate of occurrence of migration. Obviously then, as absolute population size increases (while absolute net immigration does not), the rate of net immigration will fall (table H). The typical result is that migration in these projections is constrained to be a steady, if unspectacular, contributor to population growth. The impact of net immigration on future population growth would be far more complex if rates of net immigration were projected (as are birth rates and death rates). If that were the case, it would be possible to discuss the effects of age structure and the like on future levels of net immigration. Instead, it is assumed that the amount of net immigration would not vary with changes in the size of a specific age-sex-race-ethnicity group. Also, use

of rates of net immigration would mean that increased population size would tend to result in an absolute increase in net immigration. In the current projection system, there is no association whatsoever between population size and the amount of net immigration. It is assumed that the volume of net immigration is dependent on national laws and policies, rather than on demographic factors.

Table L presents the low, middle, and high assumptions for future Spanish-origin net immigration. The high assumption is much above the middle net immigration assumption because it is the only series to include an allowance for undocumented immigration. The reasons for this are detailed in the later section of this text which discusses the net immigration assumptions. Regardless of the level assumed, Hispanic net immigration is seen to be youthful.

Table L. Projected Annual Amount of Hispanic Net Immigration, by Age: 1982 to 2080

THE EFFECTS OF ALTERNATE FERTILITY, MORTALITY, AND NET IMMIGRATION ASSUMPTIONS ON THE HISPANIC POPULATION

One value of creating alternative assumptions for each component of change (births, deaths, and net immigration) is that this enables one to quantify the consequences of variability in a given component more precisely. For instance, if a user were concerned about the possibility that net immigration might follow the low or high assumption path rather than the middle series assumption, projections are available which would enable the user to evaluate the impact of such alternatives on the projected population. The purpose of this section is to examine these consequences for the future size of the Spanish-origin population. The procedure used was to study the consequences of allowing one component of change to vary while the other two components remained at the middle assumption level.

Alternative net immigration assumptions. Table M indicates what the future size of the Spanish-origin population would be if fertility and mortality stayed at middle assumption levels; while net immigration followed the low, middle, or high scenarios. In 2000, the population of the low immigration series would be only 1.3 million persons smaller (or 5 percent) than the middle series—but the high immigration series would be larger by 5 million persons (20 percent). In 2030, the

Source: Table 5.

equivalent variation from the middle series would be 4.3 million (low immigration) and 17.5 million (high immigration); while in 2080 it would be 9.3 million and 39.5 million persons.

No matter what the level assumed for net immigration, the future Spanish-origin population would be substantially larger than it is now (table M). Even in the low migration series, the Hispanic population would triple by 2080. It would be more than six times its present size by that date if the high migration scenario were to occur.

Alternative fertility assumptions. Table N indicates what the future size of the Spanish-origin population would be if mortality and net immigration stayed at middle series' levels, but fertility followed the low, middle, or high scenarios. Through the end of this century, variations in Hispanic fertility would not greatly affect the size of the Spanish-origin population. Each of the alternative populations would be only about 3 percent, or three-quarters of a million people, different from the middle series in 2000.

The primary reason for this comparatively narrow range is that all of the population variation between the series is necessarily confined to those persons under age 18 in 2000 (i.e., those born after the July 1, 1982, starting point of the projections). With the continuing passage of time, however, the range between the alternative fertility series would increase as an ever-greater proportion of the population was made up of people born after July 1, 1982. By 2030, the population range from the low to the high fertility series is more than 10 million (table N). Again, none of that 10 million difference occurs among the population over age 47 (since they were already born by July 1, 1982). That range expands to over 20 million in 2050 and more than 41 million in 2080. Given sufficient time, fairly small persistent changes in fertility

Table N. Hispanic Population With Different Levels of Fertility: 1990 to 2080

Source: Table 6.

trends would generate a huge range in the future size of the Hispanic population.

Regardless of the future fertility level assumed for Hispanics, the Spanish-origin population will increase substantially. For instance, in spite of the fact that the ultimate high fertility assumption is not very high by historical standards (2.3 children per woman after 2050), by 2080 the Hispanic population in the high fertility series would be more than five times its present size (table N). Even if Hispanic fertility were to decrease to 1.6 children per woman by 2050 (the low fertility assumption), the population would continue to grow for almost a century and be nearly triple its present size in 2080. These results are not quite as dramatic as those described earlier for alternative net immigration scenarios, but they also demonstrate the likelihood of substantial future Hispanic population growth.

Alternative mortality assumptions. In the previous section about the effects of alternative fertility assumptions, it was pointed out that in the year 2000 the Hispanic population in the high and low fertility series each would be just three-quarters of a million people different from the middle series. This fact was presented as a demonstration of the fairly lengthy span of years necessary for substantial impact to result from large variations in fertility. In comparison, variations in mortality would have a truly minimal impact on the future size of the Spanish-origin population (table O). In 2000, the high and low mortality series would produce Hispanic populations which would be just 80,000 (0.1 percent) different from that of the middle series. Fifty years would pass before the alternative mortality series' populations would vary by as

much as the aforementioned three-quarters of a million from the middle series.

Since mortality in the high mortality series is assumed to improve at half the pace assumed for the middle series, and the low mortality series is assumed to experience rates of mortality improvement which are 50 percent more rapid than in the middle series; it is easy to recognize that tremendous variations in future mortality trends would be necessary if mortality were to have anywhere near the impact which fertility or net immigration variation would have on the number of Hispanics. It also would be difficult to construct an alternative mortality scenario in which the Hispanic population did not increase substantially during the next 100 years. Even in the high mortality series, the Spanish-origin population would double in size before 2020 and nearly triple by 2050.

Table O. Hispanic Population With Different Levels of Mortality: 1990 to 2080

(As of July 1. Numbers in thousands. Includes Armed Forces overseas. Each series uses the middle fertility and net immigration assumptions)

POPULATION PROJECTION INFORMATION BY RACE AND SPANISH ORIGIN

Although this report only presents detailed data for the Spanish-origin population, it would not be appropriate to concentrate this analysis solely on the Hispanic population. One reason is that this Hispanic information is more useful if it is examined in the context of projection information for other specified American population groups. Another reason is that, because of space limitations, little analysis of the specified race groups was shown in the national projections report. This section provides some of that analysis for interested users. Only information from the middle projection series is shown in the first part of this section. The information from the individual groups does not aggregate to the total population figures because Hispanics can be members of any race.

Population size and growth. A comparison of the Spanish-origin future population growth with that of the total population, using the middle series, demonstrates the relative rapidity of Hispanic population growth (table P). For instance, between 1982 and 2000 alone, the Hispanic population would increase 9 million or 60 percent. The total population in 2000 would be 15 percent or 36 million people larger than it was in 1982.

Table P. Total Population, by Race and Spanish Origin: 1982 to 2080

(As of July 1. Numbers do not sum to total because the Spanish origin may be of any race. Numbers in millions. Data from the middle series. Includes Armed Forces overseas)

Year	Total	Spanish origin	White non-Hispanic	Black	Other races
1982	232.1	15.8	183.5	27.7	5.9
1985	238.6	17.3	186.8	29.1	6.4
1990	249.7	19.9	192.0	31.4	7.5
1995	259.6	22.6	196.2	33.7	8.5
2000	268.0	25.2	198.9	35.8	9.5
2010	283.2	30.8	202.6	40.0	11.7
2020	296.6	36.5	204.5	44.2	13.7
2030	304.8	41.9	202.4	47.6	15.6
2040	308.6	46.7	197.2	50.3	17.3
2050	309.5	50.8	190.8	52.3	18.9
2060	309.7	54.2	184.8	53.7	20.4
2070	310.4	57.2	180.0	54.9	21.9
2080	310.8	59.6	176.0	55.7	23.4

Sources: Current Population Reports, Series P-25, No. 952, tables 5 and 6; tables 1 and 14; and unpublished data.

This means that Hispanics, who represented 7 percent of the 1982 total population, would contribute one-fourth of the total population growth between 1982 and 2000. During that same period from 1982 to 2000, the White non-Hispanic group would grow 15 million (8 percent); Blacks would increase 8 million (29 percent), and the other races population would increase 3.7 million (63 percent). The other-races group would grow the most rapidly because of its level of net immigration (tables W and Z).

Similar general results are obtained in a longer view over the next half century (comparing 1982 with 2030). The Hispanic population would grow to 42 million, an increase of 165 percent from 1982 (table P). The total population would increase 31 percent to 305 million in 2030. A third of the total growth would have been contributed by the Hispanic population. The White non-Hispanic population, however, would be only 10 percent larger in 2030. In fact, this group would commence a steady population decline around the year 2020.

The cumulative effects of such sharply different rates of growth are very evident by 2080 (table P). The total population would be one-third larger in 2080 than it was in 1982. Both the Hispanic and other races populations, however, would be quadruple their present size. The Black population would have doubled. White non-Hispanics, conversely, would number 7.5 million fewer (4 percent) in 2080 than in 1982.

Rate of population growth. Another method of analyzing population growth trends among different race and ethnic groups is to examine rates of population growth and not absolute amounts of population growth. This procedure adjusts for any confounding effect of variation in the size of different

populations. The Hispanic annual growth rate at present is about 3 percent (table Q). The total American population has not grown so quickly for a century or more. Even at the height of the baby boom (late 1950's), one of the most dramatic periods of population growth in American demographic history, the population growth rate of the United States was only 1.8 percent a year. In the middle series, the Hispanic population growth rate would not decline to that level for 30 years. Even in the lowest growth series, the Spanish-origin rate of growth would remain above the peak baby-boom level until the late 1990's (table C). There is a dramatic contrast between these indicators of rapid growth and the projected low growth rate of the Hispanic population after 2050. Thereafter, according to the middle series, the Spanish-origin population would grow more slowly than did the U.S. population during the 1930's.

The U. S. population is currently increasing about 0.9 percent per year (table Q). After 1995, the total population would grow more slowly than ever before in American history. Its rate of growth after 2040 would be virtually zero. In 2040, the Hispanic population still would be growing at the current U.S. level of 0.9 percent. The White non-Hispanic population is now growing at an annual rate of 0.6 percent (table Q). Its growth rate is projected to slow rapidly after 1990 and would become negative around 2020. The underlying reason for the post-1990 decline would be a fall in the number of White non-Hispanic births as the female baby boom cohorts age out of the prime childbearing years. The growth rate of the Black population would decline during the next 100 years (table Q). Now growing at 1.6 percent a year, the growth rate of the Black population would fall below 1 percent by 2020, and 0.5 percent by 2050. Its growth rate would have decreased to the present total population growth rate (0.9 percent) by 2020.

Table Q. Average Annual Percent Change in Population, by Race and Spanish Origin: 1982 to 2080

(Includes Armed Forces overseas. Data from the middle series)

Period (July 1 - July 1)	Total	Spanish origin	White non-Hispanic	Black	Other races
1982 to 1985	0.9	3.0	0.6	1.6	3.2
1985 to 1990	0.9	2.8	0.6	1.5	2.9
1990 to 1995	0.8	2.5	0.4	1.4	2.6
1995 to 2000	0.6	2.2	0.3	1.2	2.3

2050 to 2060	0.0	0.7	-0.3	0.3	0.8
2060 to 2070	0.0	0.5	-0.3	0.2	0.7
2070 to 2080	0.0	0.4	-0.2	0.1	0.7

Source: Derived from data in tables 1 and 14; and unpublished data.

Median age. The steady rise in the median age of the Spanish-origin population has already been described (table D). In table R it is evident that, in spite of this steady increase, the gap between the median age of Hispanics and the median age of the total population would widen during the next quarter

Table R. Median Age, by Race and Spanish Origin: 1982 to 2080

(As of July 1. Includes Armed Forces overseas. Data from the middle series)

Year	Total	Spanish origin	White non-Hispanic	Black	Other races
1982	30.6	24.1	32.1	25.5	27.2
1985	31.4	25.0	32.9	26.2	28.5
1990	33.0	26.3	34.6	27.7	30.4
1995	34.7	27.2	36.5	29.2	32.1
2000	36.3	28.0	38.5	30.2	33.5
2010	38.5	29.3	41.4	31.4	35.6
2020	39.3	31.2	42.3	33.5	37.5
2030	40.8	33.0	43.9	35.5	38.4
2050	41.6	36.2	44.2	38.1	39.6
2080	42.8	40.9	43.9	41.8	40.8

Source: Current Population Reports, Series P-25, No. 952, tables 5 and 6; table 3; and unpublished data.

century. In other words, the total population is getting older more quickly than is the Spanish-origin population. For example, in 1982 the U.S. median age was 30.6—6.5 years above the Spanish-origin median age. By 2000 the median age of the U.S. population would be 36.3 years, while that of Hispanics would be 28.0. The difference in median age would have widened to 8.3 years. This gap would reach a maximum of 9.1 years around 2010, then narrow. However, it still would remain above the present spread in median age (6.5 years) until almost 2050 (table R).

The explanation for these changes in median age is simple when an examination is made of the age pyramids for 1982, 2000, and 2030 (figures 1, 2, and 3). The Spanish-origin population structure for 1982 shows only a minor indication of the baby boom (1950's) and subsequent baby bust (1970's) which are such familiar aspects of the other groups' population structures. The boom and bust groups cause the median age of the total population to increase dramatically when the baby boom groups become older than the median age (from now to 2010). Their size pulls the median age up, and that impact is accentuated by the small size of the younger baby bust groups. The Spanish-origin median age would rise more quickly than that of the total population after 2010 because of the diminished population size, and hence, impact, of the boom and bust groups in the total population.

The median age of the U.S. population was 30.6 in 1982. The median age of Hispanics, now 24.1 years, would not reach the present U.S. level until approximately 2020. The Black populations' median age would reach 30.6 shortly after 2000. It was 25.5 years in 1982. The median age of the other-races population was 27.2 in 1982. It would reach the 1982 U.S. level of 30.6 years shortly after 1990. The White non-Hispanic groups' median age would remain 1 to 3 years above that of the total population (table R). It is also the only group whose median age would ever decline in the next 100 years. This would occur after 2040 with the dying-off of the baby boom generation.

Dependency ratios. The overall dependency ratio of Hispanics was 72 in 1982 (table S). The equivalent ratio for the total U.S. population was 63. The fact that the Spanish-origin ratio

is larger than that of the total population illustrates the point that the Hispanic population is not primarily made up of persons of working age. The overall dependency ratios of these groups would remain about that far apart through 2010. The situation changes dramatically after 2010 (table S). The overall dependency ratio for the total population would jump from 58 in 2010 to 75 in 2030. Meanwhile, the Spanish-origin ratio would only rise from 65 in 2010 to 70 in 2030. The overall ratio for the total population then would remain higher than that of the Spanish. from 2030 to 2080. The reason for the large jump in this ratio for the total population would be the transition of the large baby boom cohorts from working-age to ages 65 years and older (table S).

The elderly dependency ratio of the total population would grow slowly from 19 in 1982 to 22 in 2010 (table S). It then would increase sharply to 29 in 2020 and 37 in 2030 as the baby boom cohorts turn 65. The elderly dependency ratio of the Hispanic population would increase much more smoothly during the next 100 years. The Hispanic ratio would double by 2020 and quadruple by 2080. Even so, it would not rise to the current total population ratio of 19 until after 2020.

The Spanish-origin youthful dependency ratio would decline from 64 in 1982 to 59 in 2000 and 48 in 2030 (table S). Not until after 2030 would this ratio rise to the current level in the total population (44). Although it is considerably above

the current youthful dependency ratio of the total population, the Hispanic ratio is no larger than that of the total population was during the mid-1960's.

Because of its size, the overall dependency ratios of the White non-Hispanic population would remain close to those of the total population during the next 100 years (table S). The youthful dependency ratios of White non-Hispanics would remain a bit lower than those of the total population while the elderly dependency ratios of White non-Hispanics would stay above those of the total population. Each of these results is a consequence of the comparatively old age structure of this group (figures 1, 2, and 3). An unusual result for the White non-Hispanic population is the projected rise in its youthful

dependency ratio from 2010 to 2080 (table S). This would occur because White non-Hispanic fertility rates do not change after 2010, but the White non-Hispanic population of working age would decrease as the baby boom cohorts become 65. The result would be a more rapid decline in the population of working age than in the youthful population.

Population by age group. It was noted earlier that all the Spanish-origin age groups would experience substantial future growth; in fact all would double in size within 50 years. No age group under 65 for the total population would have done so by 2080 (table T). Another major difference is that every age group of the total population would experience periods

Table T. Projections of the Population, by Age, Race, and Spanish Origin: 1982 to 2080

(Numbers do not sum to total because the Spanish origin may be of any race. As of July 1. Numbers in thousands. Includes Armed Forces overseas. Data from the middle series)

Source: Table T.

of substantial decrease. This would not occur among Hispanics. One effect of these varying patterns is evident in table V, where a substantial rise is seen in the percent of the total population which would be Hispanic. The Spanish-origin group presently constitutes about 7 percent of the population. That percentage would rise to 9 in 2000, 14 in 2030, and 19 in 2080.

Naturally, the Spanish-origin percentage of each age group also would tend to rise. It is nevertheless striking to observe that the Hispanic population in the 45-and-over age groups would grow more rapidly than the total U.S. population of these age groups—even when the enormous baby boom cohorts of the total population move into the 45-and-over age groups. The U.S. total population aged 45 to 64 years, for

instance, would grow about 67 percent between 1990 and 2010 as the baby boom generation pours into it (table T). During the same period, the Hispanic population aged 45 to 64 years would increase 128 percent.

Perhaps a more impressive example is a comparison of the growth of those aged 65 years and older in these two groups (tables T and U). A great deal of attention has been given to the social and economic consequences for our Nation of the increase of 25 million in this age group's population from 2010 to 2030. The elderly Hispanic group, according to these projections, would grow much more rapidly. Between 1982 and 2010 it would have already tripled. In contrast, the total U.S. population aged 65 years and over is not expected to triple between 1982 and 2080. Then, from 2010 to 2030 (when

the total population aged 65 and above would grow 65 percent), the elderly Hispanic population would grow 125 percent. The percentage of the total population aged 65 years and older which is Hispanic would grow from 3 percent in 1982 to 5 percent in 2000, 8.6 percent in 2030, and almost 17 percent in 2080 (table V). The growth of the Hispanic elderly population almost certainly would have a major impact in the future on all systems of care and service to the elderly.

White non-Hispanic age groups are projected to grow even more slowly than those of the total population (table T). During the next 100 years, for instance, no White non-Hispanic group under age 35 would ever be as much as 10 percent larger than they were in 1982. Most of these youthful age groups would begin to decline in size by 2000. The White non-Hispanic groups over age 35 would increase more substantially, but all eventually would begin to decline (table T). Each age group would grow as the baby boom generation swelled

Table V. Percent Distribution of the Total Population, by Race and Spanish Origin: 1982 to 2080

(Percentages do not sum to 100 because the Spanish origin may be of any race. As of July 1. Includes Armed Forces overseas. Data from the middle series)

its size, then would decrease sharply with the subsequent replacement of this group by the smaller birth cohorts of the 1970's.

As a consequence of its comparatively slow growth, the percentage of the population made up of White non-Hispanics would fall during the next 100 years (table V). In 1982, White non-Hispanics made up 79 percent of the population. That percentage would decline to 74 in 2000, 66 in 2030, and 57 percent in 2080. Similar steady decreases would occur for every age group of White non-Hispanics. Such a decline would even occur in the 85-years-and-over age group (table V). That is remarkable in light of the fact that this particular White non-Hispanic group would more than quintuple in size between 1982 and 2050 (table T).

The Black population of every age group is projected to grow with sufficient rapidity so that their proportion of the total population of each age group would rise (table V). Still, every Black age group under 35 would experience some period of population decrease (table T). The result for these younger groups is a fairly slow rise in their percent of the total population. For example, Blacks under age 18 now comprise about 15 percent of that group in the total population (table T). That percent only would grow to 16.9 percent in 2000 and to 18.6 percent in 2030. Since all the Black groups over age 35 eventually would more than double in size, each also would come to represent a significantly larger fraction of those older age groups (tables T and V).

Projected components of population change. The Spanish-origin population is growing about three times as quickly as is the total population (table W). It would continue to increase at least three times as quickly through 2080. Differential fertility is the major cause of the higher Hispanic growth until 2030. Differences in net immigration rates are currently the second most important cause. Interestingly enough, however, after the year 2000, differences in the crude death rates would explain more of the variation in growth than would net immigration (table W). In fact, after 2030 mortality would be a more important contributor than even fertility differentials to the higher Spanish-origin growth rates. This is a counter-intuitive result because of the assumption that mortality rates for the Spanish origin and total population steadily become more similar (table B-4). Net immigration, which does not converge, would seem a more likely candidate eventually to become the primary factor in the differential growth rates. Great differences in the population age structure are responsible for these results. The Hispanic population structure, although aging, would remain comparatively young, and this would keep their crude death rate much below that of the total population — even though the two groups are assumed to become ever more similar in terms of life expectancy at birth.

The Hispanic population would not attain the 1982 total population levels of the crude birth rate until 2030, of the crude death rate until 2050, and of the net immigration rate until after 2080, if ever (table W). This is another way of illustrating the causes of the greater rates of total Hispanic population growth in the future. A further striking example

is that the Hispanic population growth rate during the next 100 years, even *without* net immigration (i.e., the birth rate minus the death rate), would be more than twice as rapid as that of the total population *with* net immigration.

The White non-Hispanic population is probably growing as slowly as it ever has (table W). It is projected to grow even more slowly during the next 100 years. Each component of White non-Hispanic growth would be less favorable than it would be for other groups in the population. That is, the White non-Hispanic crude birth and net immigration rates would always be the lowest, and their crude death rate would always be the highest of any specified group.

The Black population growth rate is 16 per 1,000. Virtually all the difference from the overall population growth rate of 9.5 is due to the higher Black crude birth rate (table W). With the passage of time, lower Black crude death rates would be responsible for more of this differential growth. The death rate would account for 25 percent of the difference in growth rates in 2000 and 50 percent of the difference in 2030. The Black growth rate and crude birth rate would not decline to the 1982 total population level until almost 2020. The Black crude death rate would rise to the 1982 level for the total population by 2030.

Births. Now about 11 percent of births in the United States are Hispanic (derived from table X). According to the middle series that percent would reach 15 by 2000 and almost 19 by 2030. There would be little subsequent change in the proportion of all births that are Hispanic (20 in 2080) because

of Spanish-origin convergence to overall patterns in both fertility rates and age structure.

In 1982, there were 2,625,000 White non-Hispanic births (table X). There would never be many more than that during any of the next 100 years. In fact, there would be a sharp drop in the number of White non-Hispanic births after 1990. From 2000 to 2080, White non-Hispanic births would remain at least 10 percent below their current levels. These declines occur despite the fact that, during the next 100 years, White fertility rates are projected to remain above their present level. The explanation for this seeming contradiction is the future diminution of the White non-Hispanic female population of

Table X. Projected Number of Births, by Race and Spanish Origin: 1982 to 2080

(Numbers do not sum to total because the Spanish origin may be of any race. Numbers in thousands. Includes Armed Forces overseas. Data from the middle series)

Source: Current Population Reports, Series P-25, No. 952, tables 2, 3, and 4; table 1; and unpublished data.

childbearing age when the baby boom cohorts move into their forties and fifties. As a consequence of lower numbers of births, the percent of all births which would be White non-Hispanic would fall in the next 100 years. The White non-Hispanic share of all births would decline from 70 percent in 1982 to 64 percent in 2000, and 58 percent in 2030 (derived from table X).

In 1982, there were 627,000 Black births (table X). Black births would tend to be more numerous in the future; although they would never be more than 10 percent above the present level. As a result, Black births as a share of all births would increase quite slowly (from 17 percent in 1982 to 18 percent in 2000 and 19 percent in 2030).

Births to other races would increase more substantially than would those of any other group (table X). This is the only group whose future number of births ever would be twice their current level (2030 and beyond). The interesting point here is, because of a lack of data, in these projections the other races' group was assumed to always experience White fertility levels (which are considerably lower than Black and Spanish-origin fertility rates). The substantial future growth in the number of other races' births must therefore be due to rapid growth of this group's population of childbearing age. The other races' births as a percent of all births would rise from 2.6 percent in 1982 to 4.1 percent in 2000, 5.6 percent in 2030, and 8.1 percent in 2080 (derived from table X).

Deaths. Less than 4 percent of all deaths in the United States occurred to the Spanish-origin population in 1982 (derived from table Y). It only would have risen to 5 percent in 2000. The percentage would rise more drastically after that time (to 9 percent in 2030 and 16 percent in 2080) because of the continued rapid Hispanic population growth coupled with the aging of that population. Even so, the Hispanic share of all deaths would remain smaller than their share of the total population of the United States.

Deaths among White non-Hispanics would always be more numerous during the next 100 years than they are at present. There were 1,675,000 White non-Hispanic deaths in 1982. That number would reach 1,936,000 in 2000 and 2,794,000 in 2050. The number of White non-Hispanic deaths eventually would begin to decline after the White non-Hispanic population begins to decrease in size. White non-Hispanic deaths as a percent of all U.S. deaths would tend to diminish because this group's share of the total population of the United States would fall.

The number of deaths in the Black population would increase in the future (table Y). However, no rapid growth in the number of Black deaths would occur until after 2010 (when the Black-baby-boom cohorts would begin to turn 65). The Black share of all deaths therefore would exhibit little increase until after that time. Deaths to Blacks would represent 11.5 percent of all deaths in both 1982 and 2010, then rise to 14 percent by 2050 (derived from table Y).

Because of their rapid population growth, the number of other races' deaths would rise quickly. They would double by 1995 and be six times their present level in 2030.

Table Y. Projected Number of Deaths, by Race and Spanish Origin: 1982 to 2080

(Numbers do not sum to total because the Spanish origin may be of any race. Numbers in thousands. Includes Armed Forces overseas. Data from the middle series)

Net immigration. Table Z presents the assumed annual amount of net immigration to the United States by age, race, and Spanish origin. Spanish-origin annual net immigration in the middle series is 143,000, almost one-third of the total net immigration assumption (450,000) used in the middle series of the National population projections. The disproportionate nature of this Hispanic net immigration is obvious when it is remembered that only 7 percent of the U.S. population now is Hispanic. About 30 percent of future annual net immigration would occur to the White non-Hispanic population. This is much smaller than their present share of the total population (80 percent). The level of Black net immigration (56,000) is consistent with their current share of the total population. The other races' net immigration of 124,000 represents 27 percent of all net immigration, about 10 times their share of the total U.S. population.

The proportion of net immigration which would occur among those over age 45 is quite small in any of these populations (table Z). Net immigration over age 65 is actually negative for the White non-Hispanic population, largely because of elderly foreign-born permanent emigration.

Table Z. Projected Annual Amount of Net Immigration, by Age, Race, and Spanish Origin: 1982 to 2080

(Numbers do not sum to total because the Spanish origin may be of any race. Numbers in thousands. Data from the middle series)

Age	Total	Spanish origin	White non-Hispanic	Black	Other races
Total	450.0	143.2	139.0	55.7	123.6
Under 18 years	139.3	43.3	48.5	18.3	32.4
18 to 24 years	76.9	34.7	15.2	9.5	20.1

ALTERNATIVE PROJECTION SERIES BY RACE AND SPANISH ORIGIN

The demographic characteristics of several race and Spanish-origin groups, based on middle series data, were described in the previous section. This section is a brief description of the effects on the total size of each such group of alternative assumptions about future fertility, mortality, or net immigration.

Lowest growth and highest growth series. The only one of these series in which the total population would double would be the highest series (table AA). In contrast, even in the lowest growth series the Spanish-origin population would double. The percentage of the total population which is Hispanic consequently would increase in all three series (table BB). The percent Hispanic was 6.8 in 1982. The Hispanic percentage of the total population is projected to reach at least 9 percent by 2000, 13 percent by 2030, and 18 percent by 2080. In the highest series, the percent of the total population which is Hispanic would be much above these minimum values because of the high share of net immigration assumed to be Hispanic in this series. In the highest series, the Hispanic share of the total population would be 11 percent in 2000, 18 percent in 2030, and 26 percent in 2080.

Even in the highest series, the White non-Hispanic population would grow quite slowly (table AA). By 2080, in the highest series, the White non-Hispanic group would be only 38 percent larger than it was in 1982 (183.5 million). The White non-Hispanic group eventually would experience a population decline in both the lowest and middle series. Given these results it comes as no surprise that there would be a decrease in the percent of the total population which would be White non-Hispanic (table BB). In 1982, 79.1 percent of

the population was White non-Hispanic (table BB). In 2000, at most, 75 percent of the population would be White non-Hispanic. In 2030 the equivalent figure would be 68 percent, and, in 2080, White non-Hispanics would constitute at most 58 percent of the U.S. population. It also is interesting to note that the White non-Hispanic share of the total population is greatest when the White non-Hispanic population grows most slowly, if at all (tables AA and BB). This is due to the fact that higher growth assumptions for any component do not increase White non-Hispanic growth as much as they increase the growth of other population groups.

In the lowest series, the Black population eventually would begin to decline; while in the highest series the Black population would more than triple its 1982 size (27.7 million) by 2080 (93.7 million). Perhaps the most striking result is that there is essentially no variation across these three series in the percentage which Blacks would be of the future population (table BB). Now 11.9 percent of the total population are Black. In 2000 that percentage would be 13.4 and in 2030 Blacks would comprise about 15.6 percent of the total population.

The other races population can be seen to increase rapidly in even the lowest series (where the other races population would double by 2030). Their share of total population would increase in all three series. This percentage would be near-identical in the lowest and middle series, but in the highest series their percentage of the population would be even higher (because of comparatively high net immigration). Their share of the total population, now 2.5 percent, would rise to 5 percent in 2030 and 7.5 percent in 2080 (table BB).

Alternative net immigration assumptions. Table CC indicates what the future size of the population by race and Spanish origin would be if fertility and mortality remained at the middle

assumption level while net immigration followed the low, middle, or high scenarios.

The Spanish-origin population in the lowest net immigration series would more than triple by 2080 (table CC). In contrast, the total population in even the high net immigration series would be just 53 percent above the 1982 figure by 2080. The juxtaposition of these rates of growth helps to explain why the Hispanic proportion of the total population would rise under all net immigration scenarios (table DD). The low and middle net immigration series yield similar percents of the total population which would be Hispanic while the high

series dramatically would increase the Spanish-origin percent of the total population. It seems that the relative growth of the Spanish origin and total population are fairly insensitive to levels of net immigration at or below the middle assumption level.

Variations in the future level of net immigration would have a minor impact on the size of the White non-Hispanic population (table CC). Until 2030, the alternative series are never more than 5 million persons apart. It is noteworthy that the high net immigration series would have the lowest future White non-Hispanic population. This unusual result is the con-

Table DD. Percent Distribution of the Total Population With Different Levels of Net Immigration: 1982 to 2080

(Percentages do not sum to 100 because the Spanish origin may be of any race. As of July 1. Includes Armed Forces overseas. Each series includes the middle fertility and mortality assumptions)

sequence of much higher White non-Hispanic emigration in that series coupled with no significant entry of White non-Hispanic undocumented immigrants. Obviously then, in the high net immigration series, there would be a substantial decline in the percent of the population who are White non-Hispanics (table DD). By 2080, in the high net immigration series, White non-Hispanics would make up only 45.9 percent of the population—compared with 79.1 percent in 1982. The percentage of the population which would be White non-Hispanic is very similar in the low and middle net immigration series, decreasing to 58 percent by 2080.

Variations in the future level of net immigration also would have a minimal impact on the size of the Black population or the Black proportion of the future population (tables CC and DD). The Black share of the total population still seems almost certain to increase.

However, both the other races' population size and its share of the total population are heavily influenced by the level of future net immigration. Nevertheless, in each series, the population size of the other races would get larger and so would their share of the total population. Even with low net immigration, the other races' population would double from 5.9 million in 1982 to 12.2 million in 2020. This group would double by 2000 in the high net immigration series (table CC).

Alternative fertility assumptions. Table EE indicates what the future size of the population by race and Spanish origin would be if mortality and net immigration stayed at middle series' levels, but fertility followed our low, middle, or high scenarios. Through the year 2000, variations in fertility would not greatly affect the size of any of these populations. The primary reason for this comparatively narrow range is that all of the population variation between the series is confined to those age groups born after July 1, 1982 (the starting date of these projections). With the continuing passage of time, however, the range between the alternative fertility series increases

substantially as an ever-greater proportion of the population is made up of people born after July 1, 1982. Fairly small persistent changes in fertility trends would generate a huge range in the future size of each group.

Table FF provides the necessary data to study the effect of alternative fertility scenarios on the composition of the future population. In terms of the percent which a particular group would be of the total population, there would be little or no effect until after 2050. There is an underlying methodological explanation for so little variation with changes in fertility levels. It is that the fertility rates of each race and Spanish-origin group were assumed to follow identical smooth convergence paths to White rates in all three fertility scenarios. The near-constancy of their relative size, regardless of the level of fertility, is a direct consequence of that assumption. The strength of that assumption is discussed in the fertility assumptions section.

Alternative mortality assumptions. Variations in mortality would have less impact on the future size of the population by race and Spanish origin than would variation in the assumptions about fertility or net immigration (table GG). Since mortality in the high mortality series is assumed to improve at half the pace assumed for the middle series, and the low mortality series is assumed to experience rates of mortality improvement which are 50 percent more rapid than in the middle series, it is obvious that tremendous variations in mortality would be necessary if mortality were to have anywhere near the impact which fertility or net immigration variation have on the size of any group. The White non-Hispanic population would be affected a bit more than would other groups by alternative mortality scenarios because of its comparatively elderly age structure (where most deaths would occur).

Table HH indicates that variations in mortality in these projections, like variations in fertility, have virtually no impact on the comparative growth of any of the race or Hispanic groups.

Source: Derived from table EE.

The explanation is the same: trends for each population group in the alternative series change in parallel fashion with their change in the middle series. Therefore the absolute number of people in a group may change dramatically under a different fertility or mortality assumption, but its size in comparison to other population sub-groups would remain approximately constant.

DETAILED ASSUMPTIONS AND METHODOLOGY

Five sets of information are required to produce these population projections using the cohort-component model.

These are: a base-year population, projected fertility rates, projected survival rates, the anticipated sex ratio at birth, and future net immigration. The assumptions and procedures by which these data are generated by single-year-of-age, sex, and race are described in the sections which follow. Once these data have been produced it is a relatively straightforward process to apply the cohort-component model and generate projections. The specific details of the procedures are described in latest national population projections.⁴

The base population. Since these projections were to be consistent with the current national projections, it was necessary to construct a July 1, 1982, Spanish-origin population by sex, race, and single year of age to 100 and older as a starting point for the projections. Such detailed information was only available for April 1, 1980. The only postcensal estimates were for April 1, 1982, and April 1, 1983. At those dates the available statistics were by sex and single years of age to 74. The following procedures were applied to these data in order to generate the required population estimate for July 1, 1982. First, the age-race-sex distribution of the Spanish-origin cohorts on April 1, 1980 was used to disaggregate the 1982

and 1983 estimates for those aged 0 to 74.⁵ For example, the race distribution of 10-year-old males in 1980 was used to

⁵Because of differences in the reporting of race between the 1980 Census and other sources of administrative data (such as births and deaths), the census counts were modified to be consistent with the Office of Management and Budget categories. The modification resulted in the addition of 6.3 million persons to the White category and 188,000 persons to the Black population. All persons added to these two groups had reported themselves to be of other races. The majority of these other race persons identified themselves as being of Spanish origin. Prior to this modification about 40 percent of the Spanish-origin population had been other races. Afterwards, fewer than 2 percent were not White or Black. This modification procedure is described in more detail in Jeffrey S. Passel, "Procedures for Producing Preliminary OMB-Consistent Modified Race Data from the 1980 Census by Age, Sex, and Hispanic Origin for States and Counties," Bureau of the Census, 1983, unpublished.

disaggregate those who were 12 in 1982 and 13 in 1983. The groups born between April 1, 1980, and April 1, 1983 were parceled out by use of the characteristics of those aged zero on April 1, 1980. The last step was to weight the April 1, 1982, and April 1, 1983, populations to yield the desired July 1, 1982, population structure for those aged 0 to 74 years.

The July 1, 1982, Hispanic population aged 75 years to 100 and over by race and sex was developed by application of survival rates from the 1982 Spanish-origin life tables to the 1980 census count of this population. The April 1, 1982, and April 1, 1983, resultant population figures each were modified to be consistent with the existing 75 years and over population totals. They were then adjusted to represent July 1, 1982, estimates of the Spanish-origin population by sex, race, and single years of age from 75 to 100 and over.

The population base for the projections was now complete. It was deemed necessary to adjust these results to minimize the effects of age heaping which existed in the April 1, 1980, Spanish-origin counts. An osculatory method was used which retained the original size of the 5-year age groups.

Net immigration. The most difficult component of population change to project with any accuracy is international migration. One reason is that the level of immigration is so influenced by changes in Federal legislation, the political environment, and the degree of enforcement of border control. Another is that emigration lies almost entirely outside the bounds of our statistical system. Because none of these factors is particularly amenable to quantitative analysis, the assumption has always been made in Census Bureau projections that changes in future international migration levels could not be predicted. As a consequence, international migration is assumed to be constant in each projection series. The alternative net immigration assumptions reflect constant immigration and constant emigration, but at different levels. The middle assumption in these projections, then, is that future net immigration will be constant, and near the levels and characteristics of measured international migration in the recent past. Until 1986, the Census Bureau did not include undocumented immigration in postcensal population estimates because of problems in measuring this component. Emigration in the estimates was set at a lower level than research suggested, in part, to offset unmeasured undocumented immigration. These projections were prepared prior to 1986 and so are consistent with the net immigration assumptions used in the national estimates and projections at that time.

The details of the construction of the migration components of the alternative net immigration assumptions are discussed in the next several sections. Each alternative is consistent with the equivalent net immigration assumption in the national population projections. The numerical value of each component is shown in table II.

Low net immigration assumption. No net immigration of Puerto Ricans, Hispanic civilian citizens (military dependents), or undocumented immigrants is assumed to occur. The annual emigration of the Spanish-origin population was estimated to

Table II. Components of Alternative Annual Net Immigration Assumptions for the Hispanic Population

(Numbers in thousands)

Net immigration component	Low net immigration assumption	Middle net immigration assumption	High net immigration assumption
Total net immigration.....	85.7	143.2	361.5

Source: Unpublished data.

be 31,000 of the total national emigration of 160,000. This figure is consistent with the revised emigration assumptions used in recent Census Bureau estimates. The 31,000 were distributed by age, sex, and race according to detailed country-of-origin data provided by the Population Analysis Staff of the Census Bureau. The final component is legal immigration and refugee admission. The annual number of such Hispanic entrants is assumed to be 116,700 (table II). These persons were distributed by age, sex, and race using (1) Immigration and Naturalization Service statistics for 1977 to 1979 which show immigrants by country of origin, age, and sex; and (2) 1980 census data on immigration during the 1975 to 1980 period by country of origin, number of Spanish-origin immigrants, and race of immigrants. The assumed level of 116,700 is just the middle assumption for this component (138,200) reduced by the ratio of the overall levels of net immigration.

Middle net immigration assumption. The annual number of legal immigrants and refugees were assumed to be 138,200. This number of persons was disaggregated by age, sex, and race using the data and procedures described above for the low series. As in the other series, no immigration of Hispanic civilian citizens was assumed. The middle assumption includes no undocumented immigration and no Spanish-origin emigration. These two components are consistent with the middle series of the national projections which also assumed no undocumented immigration and only 36,000 emigrants. These assumptions are also consistent with the methodology in use for the Census Bureau's national population estimates prior to 1986. The last component was net movement from Puerto Rico which was assumed to be 5,000. All of these persons were assumed to be White and their age-sex distribution was based upon a distribution developed by the Census Bureau's Population Estimates Branch.

High net immigration assumption. The methods for creating three of the migration components (net arrival of civilian citizens, net arrival of Puerto Ricans, and emigration) have already been described. The annual undocumented immigration of the Spanish origin was assumed to be 211,600. This is consistent with the total undocumented immigration assumption of 300,000 used in the national projections. The age and sex distribution of the undocumented Hispanic im-

migrants was provided by the Population Analysis Staff of the Census Bureau. The last component of migration (legal immigration and refugees) was assumed to be 175,900. The age, sex, and race distribution of this group is the same as that developed for the middle net immigration assumption. The actual number is consistent with the 580,000 refugees and legal immigrants used in the high migration series of the national projections.

Fertility. The fundamental intent here was to create projected Hispanic fertility rates in a manner consistent with the fertility methodology of the most recent national population projections.⁶ It seemed most appropriate to replicate the procedures developed for Blacks, another minority population. The first step, accordingly, was to calculate the single-year-of-age ratios of Hispanic to White fertility rates for 1982. Second, as was the case for Blacks, these ratios were assumed to converge linearly to unity in 2050. Lastly, at each future time the appropriate ratios were applied to the low, middle, and high alternative series of White fertility rates used in the national projections. Each racial group within the Spanish-origin population was assumed to have identical age-specific birth rates and sex ratios at birth.

Annual births by race and age cross-tabulated with Spanish origin of mother were available for 1978 through 1981 from the National Center for Health Statistics.⁷ These statistics represented 19 States prior to 1980 and 22 States in 1980 and 1981. NCHS has estimated that the 1980 and 1981 data constituted 90 percent of all Spanish-origin births.⁸ The coverage was about 60 percent prior to 1980, when Texas, New Mexico, and Georgia joined the States reporting on Hispanic fertility. The population base used to calculate birth rates was the unrounded resident Spanish-origin female population of these 22 States from the April 1, 1980, census.⁹ The fact that this was not a mid-interval population did not affect the projections, as an April 1, 1980, population was also used to construct the White fertility rates. Since the Spanish-origin fertility data were unavailable after 1981, the decision was made to average the 1979-81 information and divide by the 1980 census population. Such a procedure should generate a more stable set of birth rates for comparison with the White rates. The birth rates also were calculated for 5-year age groups because of concern about the accuracy and stability of the Hispanic statistics by single years of age. Lastly, the Hispanic fertility rates were not prepared for individual Spanish-origin racial groups because so little difference was found among the birth rates of the various Hispanic racial groups.

The 1981 information was very generously provided us by Stephanie J. Ventura of the National Center for Health Statistics.

⁸Ibid.

⁹These population figures are unrounded data consistent with U.S. Bureau of the Census, Current Population Reports, Series P-25, No. 949, *Estimates of the Population of the United States, by Age, Sex, and Race: 1980 to 1983*, (May 1984).

Not all mothers reported their origin in the NCHS statistics. The proportion who did not was 9.6 percent in 1979, 7.0 percent in 1980, and 6.4 percent in 1981. For each year these were allocated to Spanish origin by 5-year age group according to the proportion of stated origin births which were Hispanic. If, in fact, few women who did not state an origin were Hispanic, then the true Hispanic rates would be a little smaller.

The above allocation was applied separately to the 1980 and 1981 data for Georgia, New Mexico, and Texas. This was necessary because of our need to estimate the number of births in these states during 1979.

Next, the number of births in each group during 1980 and 1981 were aggregated. This was also done separately for the three aforementioned states. The births in the three States were then subtracted from the total births for each age. The ratio of the total births by age to the remaining 19 States' births by age was then applied to the appropriate age group of Hispanic births in 1979. The result is an estimate of the number of Spanish-origin births there would have been in these 22 States during 1979 if statistics had existed for Georgia, New Mexico, and Texas.

It was then straightforward to add these estimated numbers of births in 1979 to the 1980 and 1981 information, and divide by three to get the average yearly number of Hispanic births by age for 1979 to 1981. Spanish-origin fertility rates for ages 14, 15-19, 20-24, ..., 45-49 were constructed by dividing the 1979 to 1981 average births by the April 1, 1980, resident Spanish origin population of these 22 States. These were then assumed to represent Hispanic fertility levels in the entire United States.

Final registered-level White fertility statistics were available for the 1979 to 1981 period.¹⁰ Three years of birth data by 5-year age group were combined and then averaged. White fertility rates for ages 14, 15-19, 20-24, ..., 45-49 were obtained by division using the April 1, 1980 resident White female population counts.¹¹

The ratios of Spanish-origin to White age specific birth rates were calculated from the 1979-1981 rates. Each ratio was assumed to represent the middle age of its 5-year age group. The reasonableness of this assumption was verified by use of unpublished single-year-of-age data from NCHS. Geometric interpolation was used to derive the ratios for the remaining single years of age.

As was the case for Black fertility in the national projections, these ratios were then assumed to apply in 1982. Similarly, each ratio was assumed to reach 1.0 in 2050. Linear interpolation was used to obtain all the intermediate year ratios. Lastly, at each future time the appropriate ratios were applied to the three alternative series of White fertility ratios to produce future Spanish-origin central birth rates. The total

¹¹Current Population Reports, Series P-25, No. 949, op. cit.

births were assigned to sex groups with a sex ratio that was assumed to be constant throughout the projection series. The sex ratio at birth chosen for use was an average of the sex ratio of registered Hispanic births for 1980 and 1981. There was assumed to be no race differential and each race was assigned the overall Spanish-origin sex ratio at birth of 1.047734.

Mortality. The goal was to create projected Hispanic mortality rates with a methodology similar to that used in the most recent national projections. Therefore, it was assumed that Hispanic and non-Hispanic mortality first would become identical in the year 2080 (when all groups were assumed to become identical in mortality). Given the lack of a time series of historic Hispanic mortality rates, the Hispanic rates by age and sex were assumed to simply converge linearly to the White values between 1982 and 2080. These assumptions simplified the projection task of constructing a Hispanic life table for 1982 (the base year in the national projections). This problem was considerable because of the lack of data above the State level. The death rates which were developed were largely based on recent California and Medicare information for the Spanish-surnamed population. The last step was to perform linear interpolation of the base year Hispanic-White differences by sex to each of the three alternative White life tables for 2005 and 2080.

It is difficult to ascertain with any confidence the relationship between Hispanic mortality conditions and those of other Americans. One reason is the paucity of national or even regional-level mortality data for Hispanics. As yet, no Federal agency disseminates such data.¹²

One analysis has been made of mortality among the entire Spanish-surnamed population of the United States.¹³ However, it was limited to those aged 65 years and over. This research significantly contributed to the projections in two ways. First, it demonstrated that the older Spanish-surnamed population have lower death rates than Whites or Blacks. Second, those in California were found to have mortality experiences very similar to the entire U.S. Spanish-surnamed population. This result permitted the linkage, with some confidence, of the elderly U.S. Hispanic death rates from Medicare with those for the younger Spanish-surnamed which were available from California.¹⁴ These data for the Spanish-surnamed population were assumed to represent the mortality of the entire Spanish-origin population. Research has indicated that this is a reasonable assumption.¹⁵

The projections of Hispanic mortality were not done separately for Hispanic racial groups because sufficient infor-

mation did not exist. There is also some evidence that the number of Hispanics who are not White, already quite small, was actually considerably smaller than indicated in the 1980 census.¹⁶

The Hispanic life table for 1982 was based almost entirely on two data sets. One was a 1979-81 life table for the Spanish-surnamed in California constructed by the California Center for Health Statistics.¹⁷ All Spanish-surname deaths by age and sex were identified in California vital statistics information for 1979 through 1981 using the 1980 Census Spanish-surname list.¹⁸ The same list also served to derive the April 1, 1980 Spanish-surnamed population of California. The April 1, 1980 population was then adjusted to a July 1, 1980 figure under the assumption that the Spanish-surnamed population changed in the same way as did California's total population.

The other data set upon which these projections were heavily dependent was a recent analysis of mortality among the Spanish-surnamed in the Medicare file.¹⁹ This analysis also relied on the 1980 census Spanish-surname list to identify the Spanish-surnamed population. A particular strength of this analysis is that the numerator and denominator of the death rates were derived from the same data set. Another strength is that difficulties with misstatement of age (as in the census) are reduced since Medicare recipients are required to prove their date of birth. The major difficulty with using the Medicare file is that it covers only the elderly population. Finally, use was made of the Spanish-surnamed infant mortality rate from Texas in 1980.²⁰

The projection technique necessitated the creation of age-sex specific death rates up to age 100 for 1982. Ages 0, 1 to 70, 70 to 95, and 95 and over were constructed using different data or methods. The construction of each of these groups is described in the following sections.

The death rate by sex for age 0 was developed as an average of the infant mortality rates available for 1980 from Texas and 1979-81 from California. This procedure was adopted even though just the California rates for ages 1-4, 5-9, ..., 65-69 were used. One reason was the uncertainty associated with reported Hispanic infant mortality rates.²¹ Another was a

recent analysis which suggested that under-reporting of infant deaths may be especially prevalent among Hispanic births where at least one parent was foreign born.²²

Age-specific death rates for 70-74 to 90-94 were calculated by splicing the trend in the 1977-79 Medicare death rates onto the California data for age group 65-69. Specifically, the ratio in the Medicare file of the 70-74 to the 65-69 death rates was applied to the California rate for age 65-69. This modified rate for age 70-74 was scarcely different from the original California data. The differences over age 80 were more substantial. Mortality rates by sex for those aged 95 and over were adapted from a set of factors based on research done by the Office of the Actuary of the Social Security Administration.²³ These same factors were used for the total population by race in the national projections.

This complete set of age-sex specific death rates for 1979-81 were assumed to represent the entire Spanish-origin population of the United States in 1982. This assumption was made because the data from the Medicare file show that Hispanic death rates in California were slightly lower than the overall Hispanic rates. Therefore, with continued mortality improvements, the 1979-81 California data probably were close to the national rates for 1982.

There is insufficient data available to attempt to determine if Hispanic mortality rates are converging to White rates or to establish the tempo of any such convergence. The assumption in these projections was that the 1982 Hispanic White differences in mortality would smoothly narrow to zero by 2080. In 2005, the differentials would be .765306 of their 1982 levels. Hispanic death rates in 2005 were developed by applying the reduced differentials to the White levels in the low, middle, and high mortality series used in the national projections. Of course the Hispanic death rates in 2080 are identical to the White rates for 2080.

All of the mortality rates thus produced for 1982, 2005, and 2080 were then used to generate life tables by single years of age and sex from which survival rates were substantially calculated. Finally, survival rates for the intermediate years from 1982 to 2005 and 2005 to 2080 were obtained by geometric interpolation.

EVALUATION OF DATA QUALITY

While the generation of these future Hispanic population figures was straightforward, there are a number of uncertainties about the adequacy of both the base data and the assumptions used in the creation of these projections. The primary areas of concern are briefly summarized here.

One difficulty is the fact that all the existing data for the Hispanic population contain some elements of uncertainty. For instance, the base population is the 1980 census count by age, sex, and race of the Spanish-origin population. These data show more evidence of age heaping than exist for other major groups. The race data, especially for Black Hispanics, have

been shown to contain inaccuracies also.²⁴ Furthermore, a small fraction of the Spanish-origin population was not enumerated in the 1980 census.²⁵

The accuracy of these projections is also influenced by differentials in White and Hispanic census undercount. The reason is the widespread use of Hispanic-to-White ratios in the construction of the fertility assumptions. It is almost certainly true that the underenumeration of Hispanic women was greater than that of White women.²⁶ As a consequence, the Spanish-origin fertility rates used in these projections would tend to be too large. That is because all of the women of childbearing age were not included in the denominators used to calculate the fertility rates.

A related difficulty is the uncertainty about the true current number of Hispanic births. As only registered-level birth information exists, there is no way at present to ascertain the completeness of coverage of Hispanic births. The accuracy of our comparison of Hispanic and White fertility partly depends on the extent to which these groups vary in the completeness of their birth registration. If Hispanic births were not as completely registered as White births, then Hispanic fertility rates could be slightly too low and appear to be closer to the White rates than was truly the case. Conversely, it might be the case that some of the Hispanic births registered in this country occur to women who do not intend to stay permanently. The effect would be to inflate Spanish-origin birth rates because these births would be erroneously attributed to the U.S. resident Hispanic population. Finally, the proportion of stated origin births which were Hispanic was used to derive the proportion of not-stated origin births which were Hispanic. The validity of that assumption is not clear.

More important to the ultimate accuracy of these projections is our ignorance about the likely future trend of Hispanic birth rates. Because Hispanic fertility statistics have been collected for only a few years, we cannot tell if the current Hispanic birth rates will converge towards the fertility rates of other groups, stay in their present relationship, or even diverge away from the fertility patterns of other groups. In this projection the assumption has been made that convergence of Hispanic fertility rates to those of other groups will occur.

Convergence was also assumed to occur in future mortality trends. This assumption is not so critical because Hispanic mortality already seems to be quite close to the present levels found among the non-Hispanic White population. Only if there actually were little or no future improvement in Hispanic fertility would the projections be affected greatly.

The available Spanish-origin mortality statistics are of lesser quality than the fertility data. One reason is that no national Spanish-origin data exist. However, a number of studies for California and Texas, plus research at the Census Bureau on a national data set for the elderly, provide evidence that the assumptions about current Hispanic mortality levels are reasonable. It is important to realize that this work does rely

on the assumption that mortality among the Spanish-surnamed is identical to mortality among all Hispanics.

Net immigration is the demographic component where our assumptions are most tenuous. Future migration flows are very dependent on the macro-level effects of any number of political, legal, social, and economic factors. The number of refugees in some future year or changes in immigration legislation are really not predictable at all. Because of such difficulties, Census Bureau projections have always contained the assumption that future migration will be identical to migration trends of the recent past.

Net immigration in the middle series also includes an assumption that there will be no permanent undocumented immigration in the future. This is probably not correct, but it is consistent with the Census Bureau's national population estimates and projections done before 1986. Until then, no allowance was made for undocumented immigration because there were no adequate measure of the component. As is true of our base-year population and fertility assumptions, the result of our net immigration assumptions is likely a tendency to make these projections of the Hispanic population somewhat conservative.

Finally, an implicit assumption of these projections is that all children of Spanish-origin mothers will consider themselves to be Hispanic. Given the existence of intermarriage with non-Hispanic groups there is at least a possibility that some mixed-heritage children would identify with a non-Hispanic group. This possibility exists in our race projections, but is of greater potential interest in Hispanic projections since intermarriage is a more frequent occurrence among the Spanish origin.²⁷

The net effect of these limitations is to produce projections of the future Hispanic population which are somewhat conservative. It is quite possible that the future growth of the Spanish-origin population will be more rapid than is indicated in the middle series.

CONSTRUCTION OF SPECIAL POPULATIONS

The projections in this report all pertain solely to the total future United States population including Armed Forces overseas. Appendix tables D-1 and E-1 provide users with the information necessary for the derivation of several special populations. The specific derivation procedures are described below.

Resident population. This is obtained by subtraction of the Armed Forces overseas population (table D-1) from the appropriate projection series in tables 2 to 8.

Resident civilian population. Subtraction of the entire Armed Forces population (table D-1) from the relevant projection series in tables 2 to 8 will yield this population.

Resident civilian noninstitutional population. Application of the ratios in table E-1 to the pertinent projection series (tables 2 to 8) generates the noninstitutional population. Subtraction of the Armed Forces population then produces the resident civilian noninstitutional population.

AVAILABILITY OF MORE DETAILED DATA

For each of the 30 series, the basic product of our methodology is a set of unrounded population counts by single years of age, sex, and race, for each year from 1983 to 2080. Fertility, mortality, and net immigration statistics were also produced with the same degree of detail. Most of these data are not published, but all of them are available at cost from the Bureau of the Census, either in hard copy or in machine-readable form. Further information may be obtained by writing to the Chief, Population Division, Bureau of the Census, Washington, D.C. 20233.

Table B-1. Five-Year Survival Rates, by Age and Sex, for the Hispanic Population: 1982 to 2080— Continued Part C. High Mortality Series

Table with columns for Initial age, Terminal age, and survival rates for various years (1985 to 2025) and life table survival rates for 1982, 2005, and 2080. It is divided into sections for Both sexes, Male, and Female.

Table B-2. One-Year Life Table Survival Rates and Life Expectancies, for the Hispanic Population
 Part A. 1982 and 2005 (Middle Mortality Series)

(See text for discussion of methodology, assumptions, and meaning of symbols)

Initial age	Terminal age	1982 survival rates			1982 life expectancy at initial age			2005 survival rates			2005 life expectancy at initial age		
		Total	Male	Female	Total	Male	Female	Total	Male	Female	Total	Male	Female
