Helping You Make Informed Decisions

U.S. Department of Housing and Urban Development Office of Policy Development and Research

U.S. Department of Commerce Economics and Statistics Administration U.S. CENSUS BUREAU

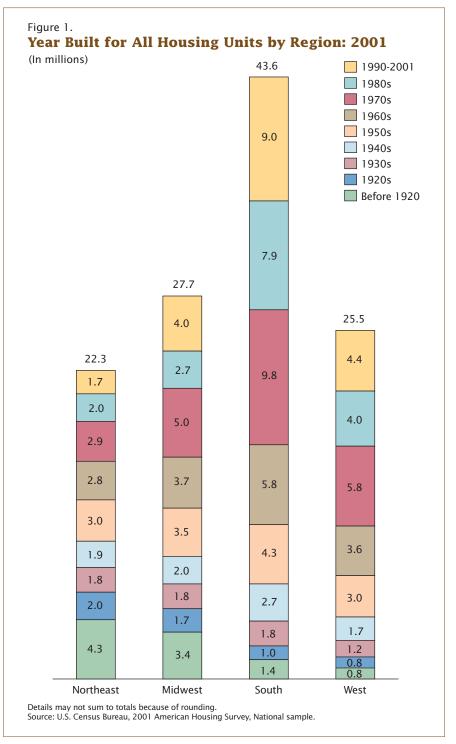

INTRODUCTION

Although the United States is more than 200 years old, its housing inventory is young. In 2001, just 8.3 percent of all American hous—ing was built before 1920.¹ This report examines housing units built 82 years or more ago (which are referred to as old units), and compares their characteristics with those of units built after 1989 (which are referred to as new units). The data are from the 2001 American Housing Survey (AHS), National Sample.²

Old housing is important for several reasons. Despite its small proportion of the total housing stock, old homes account for about 10 million housing units and were the primary residence of 8.6 million households. Because of their age, these units may present particular problems in housing quality and safety, but they may also have unique characteristics (aside from any historical significance) that could make them desirable homes. Finally, given that the median price of new single-family homes sold in 2001 was \$175,200, these old houses may provide more affordable opportunities for homeownership.3

This report is organized in three sections. The first introduces the basic statistics on the age of the nation's housing stock. The

second section compares the characteristics of old units with those of recently constructed homes, helps identify what is unique about old housing, and shows some information about the occupants of both old and new units. The third section deals with losses of old units from the housing

inventory, and examines the reasons for and rates of losses of residences built before 1920. In addition, detailed tables with the characteristics of total, old, and new units can be found at www.census.gov/prod/2004pubs/h121-04-1.pdf.

^{&#}x27;The estimates in this report are based on responses from a sample of the population. As with all surveys, estimates may vary from the actual values because of sampling variation or other factors. All comparisons made in this report have undergone statistical testing and are significant at the 90-percent confidence level unless otherwise noted.

²The population represented (the population universe) is the occupied and vacant noninstitutional housing stock of the United States. Units that are in noninstitutional group quarters (such as college dormitories) are also excluded.

³U.S. Census Bureau, "Median and Average Sales Prices of Houses Sold in United States," New Residential Sales, October 25, 2002, www.census.gov/const/www/newressalesindex .html (May 14, 2003).

SETTING THE STAGE

The Northeast had the smallest supply of housing in 2001— 18.8 percent of the nation's total. Within the Northeast, 19.1 percent of housing was old, while 7.8 percent was built in 1990 or later. The Midwest ranked second in total housing—23.3 percent. It also contained a relatively high proportion of old units in its stock (12.1 percent) and a low proportion of new (14.5 percent). The largest region was the South (36.6 percent). There, just 3.2 percent of housing was old, and 20.7 percent was new. For the West, the figures were 21.4 percent of the nation's supply, with 3.2 percent of that being old and 17.5 percent new.

In 2001, the Northeast was home to 43.4 percent of the nation's stock of about 10 million old homes. The Midwest accounted for about one—third of the total (34.2 percent), and the South (14.2 percent) and West (8.3 percent) trailed with the remainder. The Northeast's preeminence probably reflects its earlier period of settlement.

The large majority (78.1 percent) of American housing was inside metropolitan areas.⁴ However, as Figure 2 reveals, homes built before 1920 were more likely to be outside metropolitan areas than more recently constructed homes. Starting in the 1960s, half or more of American residences were built in the suburbs. Just 30.8 percent of the old units are in suburban areas.

CHARACTERISTICS OF OLD AND OF NEW HOUSING

This section compares the characteristics of housing units built before 1920 (old units) with those of units built 1990 or later (new units).⁵ Units built in the years between 1920 and 1989 are excluded from this analysis, so a clearer picture of the differences that now exist between old and new units may emerge.

Structure Type

Most old and new housing units are "1, detached" units, that is, site—built, modular or prefabricated freestanding houses (Figure 3). This sort of construction is more common among old units (63.0 percent) than new (57.9 percent). However, new homes are more often single—family residences (83.2 percent) than old homes

(69.9 percent). Besides the 1, detached structures, single–family residences include 1, attached units (townhouses) and manufac—tured housing units (mobile homes). This large proportion of newly built single–family homes is partly due to the introduction of manu–factured housing as a type of home construction after 1920.6 Manufactured homes, which are almost entirely single–family units,

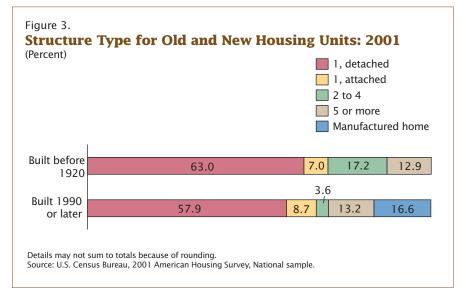

Structure types include:

- 1, detached units (site built, modular, or prefabricat ed houses)
- 1, attached units (townhouses or rowhouses)
- Manufactured housing (mobile homes)
- Units in multiunit structures (apartments)

⁴ See www.census.gov/hhes/www/ahs.html the definition of metropolitan areas as well as for other terms used in this report.

[&]quot;"Survivor" bias affects the current distribution of the characteristics of old units. Old buildings that are still in existence may have been retained because they were better in some way—size, location, quality—than their contemporaries. Thus, the distribution of characteristics of old homes in 2001 is likely to be different from what it would have been at the time the units were originally built.

⁶Manufactured homes with bathrooms were first built in the 1940s. Earlier models date to the 1920s, but were intended to be vacation units. Manufactured Housing Association of Oklahoma, "History," Welcome to MHAO, n.d., www.mhao.org/history.asp (May 21, 2003).

make up 1 in 6 (16.6 percent) of the residences built in 1990 or later. When manufactured housing is subtracted from new units, the proportion that are single—family residences falls to 79.8 percent, still larger than the 69.9 percent among old units.

Apartment buildings with fewer than five units are an important component of old housing. While these units constitute 17.2 percent of old units, they account for only 3.6 percent of new construction. The AHS does not reveal whether these older structures were built with four or fewer apartments, were originally single–family residences that were subsequently subdivided, or were rooming houses that had more than four residences that were consolidated over time.

Comparing structure type with geographic variables shows three main concentrations of old residential units:

- 1, detached houses outside metropolitan areas in the Midwest (about 12 percent of all old units)
- Units in multiunit buildings in metropolitan central cities in the

Northeast (also about 12 per-cent)⁷

 1, detached houses in the Northeast suburbs (10.6 percent of the total)

Each of these categories accounts for at least 1 million units (Table 1). The remaining combinations are variations of region, structure type, and metropolitan status, with none making up as much as 10 percent of the total stock of old units.

For new units, 1, detached houses in the suburbs of the South is the largest category with 17.3 percent (3.3 million units) built in 1990 or later; no other grouping accounts for at least 10 percent of the new homes.

Unit Size

Generally, old houses are some—what smaller than new houses, but old houses do tend to be larger than new, manufactured homes (Table 2). Attached units and apartments in multiunit structures also are more likely to be smaller in old structures than new. However, the square footage figures do not tell the whole story.

The number of rooms offers more information on the space available in old and new homes.8

About 77 percent of all singlefamily, detached units (old, new conventional, and new manufactured housing) in 2001 have five to eight rooms. While 22.2 percent of new manufactured houses have four or fewer rooms, only 11.2 percent of old units and just 5.5 percent of new conventional, detached units fall into this size category. Larger homes with nine or more rooms account for 16.7 percent of new detached units and 11.4 percent of old detached homes; only 2.1 percent of new manufactured housing are of this size.

Apartments in old and in new multiunit buildings tend to contain three to five rooms (76.3 percent of the old and 87.9 percent of the new). But 10.2 percent of old units have two or fewer rooms, compared with 2.5 percent of the new. About 13.5 percent of the old units have six or more rooms, compared with 9.7 percent of the new. Although apartments in old buildings make up only 10.4 percent of the country's entire supply of multiunit residences, they account for about 20.2 percent of all one or two room apartments.

Structural Characteristics

Old homes have many distinguishing structural traits, and these often vary by region. Figure 4 shows structural features in old and new single–family, detached homes, by region. (Only detached units appear in these charts because of the small number of other structure types in some regions.)

An immediately noticeable trait of old houses is their height. In all regions, residences built before

⁷There is no difference between the percent in this group and in the previous category.

⁸The count of rooms excludes bathrooms, laundry or utility rooms, pantries, and unfinished rooms.

¹Only units reporting square footage included in calculations.

1920 are more likely than new houses to contain more than two floors, and in both the Northeast and Midwest, the majority of old houses have three or more stories. (This holds true for new houses in the Northeast.) While a consider—ably smaller fraction of Southern and Western houses have more than two stories, old homes are still much more apt to have more stories than those recently constructed.

Garages and carports are other distinguishing traits. Before 1920, private automobiles were the exception, not the rule, so many old homes had no need of a

shelter for a car when they were originally built. By 2001, how—ever, more than half of all old homes (except in the South) had a garage or carport. New homes incorporate this feature on a rou—tine basis, ranging from 77.5 per—cent in the Northeast to 90 percent or more in the Midwest and West.

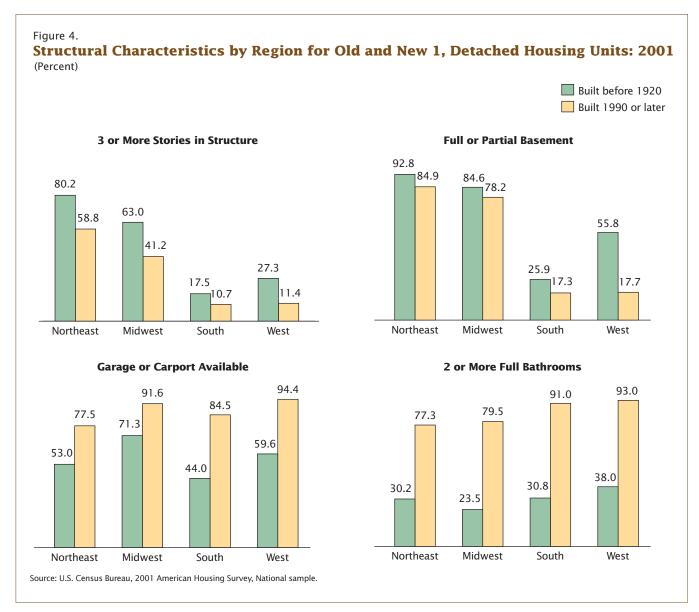

Within all regions, basements (either full or partial) are more often found in old houses than those built in the 1990s or later. There is also a marked regional variation in the presence of basements. Homes in the Northeast and Midwest are much more likely than homes in the South and West to have basements.

Multiple bathrooms are another recent characteristic. Nationwide, only 28.3 percent of old houses have two or more full baths, while in new homes, a minimum of two complete baths is common—87.7 percent (Table 3). Nearly half

Note: Details may not sum to totals because of rounding.

Source: U.S. Census Bureau, 2001 American Housing Survey, National sample.

[°]There were 8.1 million automobiles regis—tered in the United States in 1920, U.S. Department of Transportation, "State Motor Vehicle Registrations, by Years, 1900–1995," Highway Statistics Summary To 1995, February 19, 2003, www.fhwa.dot.gov/ohim/summary95/mv200.xlw (May, 15, 2003); there were 24.4 million families, U.S. Census Bureau, Fourteenth Census of the United States Taken in the Year 1920, Vol. 2, Population: General Report and Analytical Tables, U.S. Government Printing Office, Washington, DC, 1922, p. 1267.

(46.2 percent) of detached units built before 1920 contain just one full bathroom and no half baths; the comparable figure for new units is 6.3 percent.

Vacant Units

The great majority of housing units are occupied, but old structures are slightly more likely than newer ones to be vacant (10.8 percent compared with 9.1 percent).¹⁰

Only in the Northeast is the difference in vacancy rates between the old and new stock not statistically significant (Table 4).

Vacant units built before 1920 are not as likely as new units to be part of the active housing market; 43.0 percent of old vacant units are active as compared with 55.0 percent for new units. New vacant units are also more likely than the old to be intended for sporadic or seasonal use — 31.9 percent versus 23.5 percent.

Among old vacant units, 33.5 percent are sitting idle with no current plans to market or other—wise occupy the property. This compares with 13.1 percent of the vacant units built in 1990 or later. This discrepancy is particularly marked among units in multiunit structures, with 26.2 percent of old vacant units, compared with 2.8 percent new vacant apartments sitting idle (Table 5).

Old units also tend to remain vacant longer than new homes. The units in old structures consistently are more likely than those in new buildings to have been empty for 2 years or more, regardless of the reason for vacancy (Figure 5).

¹⁰In this discussion of vacant units, "Usual Residence Elsewhere" cases—which are ordinari—ly tallied as vacant units—are excluded since the survey does not collect all relevant information for these units. These account for 18.3 percent of new vacant units and 12.4 percent of old.

Source: U.S. Census Bureau, 2001 American Housing Survey, National sample.

Vacant units include:

- Active units, those for sale, for rent, for sale or rent, or sold or rented, but not yet occupied
- Sporadic or seasonal units, those intended only for seasonal use, or held for occasional use through out the year
- Idle units, those used for storage of personal effects, held for the occupancy of a janitor or caretaker, vacant while being remodeled, held during probate or litigation, or other units held off the market by the owner

Likewise, the proportion of old units that report only short vacan—cy intervals (less than 6 months) is smaller for each vacancy type than the corresponding figure for new housing units.

Heating and Cooling

Warm-air furnaces are the most commonly used heating equipment

in both vintages of residential units (Figure 6). Differences in available technology when the buildings were originally built may have helped create the distinct patterns in the equipment and fuels in use for old and new structures. Specifically, new structures rely more heavily on more modern central systems, particularly heat pumps and built—in electric units, while the steam or hot water systems found in older homes are less prevalent.

As with the presence of base—ments, regional differences in heat—ing systems are evident: 71.0 per—cent of U.S. homes of all ages with steam or hot water heating sys—tems are in the Northeast, with 46.1 percent of homes that are heated in that region using this type of heating equipment.

Because the Northeast also has the largest number of homes built before 1920, this could explain the disproportionate use of steam heating in old residences. But,

even within the Northeast, housing age plays a part in the choice of heating equipment type, with old units about twice as likely as new ones to employ steam or hot water heating (54.7 versus 27.5 percent) (Table 6).

The type of heating equipment also may dictate the type of heating fuel used. New homes heat with electricity at about five times the rate of old homes (44.9 percent, compared with 9.0 percent),

Types of heating equipment include:

- Central, these deliver heat to all or most rooms in the unit and include warm-air furnaces, heat pumps, steam or hot water systems and built-in electric units.
- Other (or noncentral), these heat only one or two rooms and include portable heaters, room heaters, fire places, stoves, and the like.

partly because of the more frequent use of heat pumps and built—in electric units in the new structures. In addition, the two equipment types used to heat 80.8 percent of old homes—warm—air furnaces and steam or hot water systems—seldom use electricity as a

fuel: just 5.3 percent of the warm—air furnaces and 2.2 percent of the hot water systems in old struc—tures heat with electricity (Table 7). Of homes built in 1990 or later, 72.2 percent use either warm—air furnaces or hot water systems; 28.7 percent of these warm—air

furnaces heat with electricity as do 7.5 percent of the hot water systems.

Because residential air conditioning equipment was not marketed until the 1920s, nearly all old homes were built without this feature.11 By 2001, 20.2 percent of old residential units had central air conditioning installed, while 80.6 percent of new homes were built with central air or had it installed after original construction. Reliance on room or window units for cooling is much more common in old construction than in new. Old homes are about five times as likely as new to use only room units for cooling rather than a central system (43.8 percent and 8.3 percent, respectively) (Table 8).

Home Value

Homeowners living in old structures tend to have less expensive homes. In fact, the medians in the detailed tables of this report (\$98,793 for old and \$154,233 for the newer units) understate this difference, because units built in 1990 or later include manufactured homes, whose median value (\$40,007) was considerably below the value for other units built in

1990 or later. Figure 7 provides a more accurate comparison of values by examining the distribution of values for both vintages of single–family, detached units. The median values for detached, owner–occupied units were \$98,794 for old homes and \$183,502 for new houses.¹² While

50.9 percent of old houses have an estimated value of less than \$100,000, only 14.1 percent of new houses are valued below that point.

Table 9 expands on these data by comparing the median value of single–family, detached homes across the four census regions. In each region, the median value of new homes is considerably higher than the old.

Table 8.Old and New Housing Units by Room Air Conditioners and Central Air Conditioning: 2001

¹²The median value of all old owner—occupied units was not significantly different from the median for old, 1, detached owner—occupied units.

Upkeep and Housing Condition

In some ways, old homes are in worse condition than new structures. Table 10 summarizes the data for single-family (attached and detached) units and for units in multiunit buildings for several types of housing problems. (Manufactured housing units are excluded because these units may have different types and quantities of problems than conventional construction, and are not part of the old unit housing stock.)

In 2001, survey respondents reported more of most of the types

of physical problems in old hous—ing rather than new. Units in old and new multiunit buildings did not differ in terms of problems with hallway lights or railings in common stairways. About 1 in 4 old apartments (23.0 percent) are in buildings with boarded—up, broken, or barred windows some—where in the structure.

Other data in the table show that old units lack complete plumbing or kitchen facilities more often than new units, and that old single—family and multiunit residences are more likely than their new counterparts to contain one or more rooms that have no working electrical outlet. The proportions of units with exposed wiring are not different within the same structure types.

Old homes generally have proportionally more problems. Water leaks from outside sources pose a particular problem for single-family homes (either detached or attached) built before 1920. Although old units account for only 8.4 percent of all single-family structures, they account for 13.7 percent of leaky roofs and 18.3 percent of wet basements that were reported in such homes. Only two types of equipment breakdowns occur at the same rate in old and new units: water supply breakdowns (for single-family

homes) and flush toilet break-downs (for multiunit buildings).

Lead-based paint is one housing problem unique to older structures. The Consumer Product Safety Commission estimates that about two-thirds of the homes built before 1940 may have contained lead paint (lead was eliminated from house paint in 1978).¹³

While this hazard is not measured directly in the AHS, peeling paint or broken plaster in old buildings may imply exposure to surfaces coated with lead-based paint.

Home Repairs, Improvements, and Remodeling

After enduring at least 80 years of wear and tear and lacking the amenities of new housing styles, old structures offer many opportunities for home repairs, improvements, and remodeling.

¹URE Usual residence elsewhere.

²Units for which the data are not reported are excluded from the base of the percentage, therefore the base for each statistic may differ.

¹³U.S. Consumer Product Safety Commission, "CPSC Warns About Hazards of "Do It Yourself" Removal of Lead Based Paint: Safety Alert," CPSC Document #5055, n.d., www.cpsc.gov/cpscpub/pubs/5055.html (July 17, 2003).

Only 17.7 percent of homeowners in old homes report paying out nothing in an average year on maintenance; the figure for new homes is 36.6 percent. Among homeowners who estimate spending anything, on average, for maintenance, those in old structures tend to spend somewhat more: the medians are \$509 annually in buildings built before 1920 and \$338 for the homes built in 1990 or later.

Major replacements, improvements, or remodeling are uncommon events, regardless of the age of the structure. Table 11 compares the frequency with which selected jobs are undertaken in the last 2 years for both old and new one-family, detached owner-occupied units. For most of these particular jobs, the old houses are somewhat more likely to have undergone the work than the new. The exception is air conditioning. Perhaps because so many new homes are in the South, new and old homes did not differ in the

rates of adding or replacing central air conditioning.

Occupants

New homes tend to have younger homeowners. New homes are more likely to have owners under the age of 25, 25 to 34, and 35 to 44 than are old homes (Figure 8). In contrast, old homes have proportionally more owners 55 to 64, 65 to 74, and 75 and over than do new homes. Owners 45 to 54 years old account for a similar proportion of owners in old and new units.

The picture for renters is more complex. For three age groups (25 to 34, 35 to 44, and 65 to 74 years), there is no difference between those in old and new units. Households in old units have a lower proportion of both the youngest and oldest renters and are more likely to contain householders aged 45 to 64 years than those in newly built structures.

Households living in properties built before 1920 are no larger generally than those in new build-ings. In fact, among homeowners, the median household size is smaller—2.3 occupants in old units and 2.6 in new. For renters, the median household size is 1.9 for both structure age categories.

One–person households occupy a larger share of some types of old units than they do of the new (Table 12). Homeowners in single–family, detached houses and renters in multi–apartment build–ings are more likely to live alone in old buildings than in new. For house owners, the proportions are 23.6 percent and 10.5 percent, respectively. For renters, 47.7 percent live alone in old apartments as compared with 41.7 percent in new units.

People in new homes moved in more recently than those in old buildings.¹⁴ The median length of residence is 3 years for owners of

new homes and 14 years for owners of old structures. For renters, the figures are 1 year for new units and 3 years for old.

Figure 9 provides more detail on the topic. It is noteworthy that about 1 in 4 (23.7 percent) of the owner-occupied buildings constructed before 1920 have an owner who has lived there at least 32 years.

Income and Household Finances

Households in old units generally have lower incomes than those in new units. Table 13 shows median income for homeowners and

renters by three age categories. In each of the categories, homeown—ers in units built before 1920 report a lower median income than owners in new buildings. For renters, however, the median income of the elderly (65 and older) is about the same for those in new and in old homes. The remaining two renter age cate—gories show lower income levels for households in old buildings. 15

Old buildings offer two major financial attractions for households with lower incomes. First, the lower median home value for old homes allows more opportunities for lower–income households to

become homeowners. Second, older properties are often less expensive on a day-to-day basis, based on the figures for monthly housing costs.

Figure 10 shows the median monthly housing costs paid by owners and renters in the three householder age categories used in Table 13. As with income, the median monthly housing costs for homeowners is smaller in each age category for households in structures built before 1920. The same relationship is true for renters. Thus living in old buildings can help households lower their housing costs.

Housing burden is a measure that compares income and housing costs. Generally, households that pay 30 percent or more of their income for housing are considered to have a high housing burden. Based on this standard, none of the three age groups of homeowners in either old or new structures has a high median housing burden (Table 14). The median monthly housing burden for owners is about 21 percent, except for the 35-to-64-year-olds who, in old units, have the lowest median burden (18 percent) of all age, tenure, and structure age combinations. Owners in the same age range who live in new homes have the second lowest burden (19 percent).16

Renters devote a larger share of their income to paying for shelter than homeowners. For renters under the age of 35, the median is 31 percent, while for those 35 to

¹⁵There is no difference in the median income for the group of renters under 35 compared with renters 35 to 64 in old homes. The same is true for these age groups of renters in new homes.

¹⁶The housing burden of owners 65 and older in new buildings is not significantly different from that for owners 35 to 64 in new homes.

64 years old, the median drops to about 25 percent. For elderly renters (those 65 and older), how-ever, the median soars to around 45 percent. The three age groups of renters show no difference in

housing burden based on the age of the building they occupy.

Generally, owner households in pre-1920 vintage buildings are less likely to have a mortgage (Table 15).¹⁷ Only the youngest

homeowners show no significant difference in the proportion with a mortgage between the two age groups of homes. The same

¹⁷In this discussion, the term mortgage refers to both regular mortgages and home equity lump sum loans.

relationship exists when comparing old homes with only conventionally built new homes, that is, all new units except manufactured housing. New manufactured homes less frequently carry a mortgage than new conventional units for the two younger age groups, but there is no statistically significant difference for owners 65 years old and older. For homeowners under 35 years old, even those in old units (84.1 percent) are more likely to have a mortgage than the similar age group in new manufactured housing (69.6 percent).

LOSSES IN OLD RESIDEN-TIAL BUILDINGS

Reasons for Losses

The first Census of Housing in 1940 recorded 20.6 million hous—ing units as built before 1920.¹⁸ A little more than 60 years later, the count was down to 9.8 million (in 2001). Many factors contributed to the loss of old units—demolitions (including urban renewal), fires, floods, storms, general decay, the merging of smaller units to create larger homes, and

conversions of housing units to various nonresidential uses.

Censuses of Housing do not measure why these losses occurred between 1940 and 2001, but the AHS can provide a look at why old units fell out of the inventory between 1997 and 2001.¹⁹

Data on losses were developed from a comparison of the status of the same addresses and units as reported in 1997 and 2001. A unit is considered a loss if it was used as housing in 1997, but not in 2001. Because this method

produces only a gross number of losses, this number cannot be subtracted from the 1997 estimate of old units to provide the 2001 estimate of existing old units. This simple comparison is not possible, partly because some units in structures built before 1920 were also added to the housing inventory between 1997 and 2001 through several processes.

Although it may seem impossible to create more old units, they could increase between 1997 and 2001 through the rehabilitation of, or conversion to residential use of old structures, or the splitting of existing units in old buildings into more housing units. In addition, the weighting of the sample may have changed between 1997 and 2001 for individual units based on their characteristics and the overall survey results for the year. Reporting error in the year-built data also confuses attempts to track units over time. Since the

reasons for adding units were generally less fully explored in the AHS than the reasons units were lost from the inventory, this report examines the losses and does not attempt to derive a complete accounting of the disposition of old units between 1997 and 2001.

Table 16 outlines the 2001 status of units that were reported in 1997 as built before 1920. The losses are split between those resulting in the complete removal of the unit and those where the unit retains the potential to return to the housing inventory.

The categories of "mergers" and "structural conversions" are traditionally treated as permanent losses for the unit, even though the structure that contained the unit remains. Thus these categories might also be considered temporary losses since the possibility exists for the unit to be reconstituted from the space within the building.

The catch-all "other" loss category for permanent losses includes situations where the sample unit was removed or replaced with another unit but no explanation was provided for the loss of the original unit, as well as all the units described as "other" permanent losses. The "other" loss category for temporary losses includes units converted to group quarters (rather than housing units) and units now reported as "under construction," which may be either misclassifications of structures being remodeled or replacement structures. The true classification of these "under construction" units should be resolved when their 2003 data are reviewed.

A small number (fewer than 10 unweighted cases) of old housing units from 1999 were categorized as being "unable to locate" in 2001. These cases may also be losses. However, without more compelling proof of their status,

these cases are not tallied with the losses.

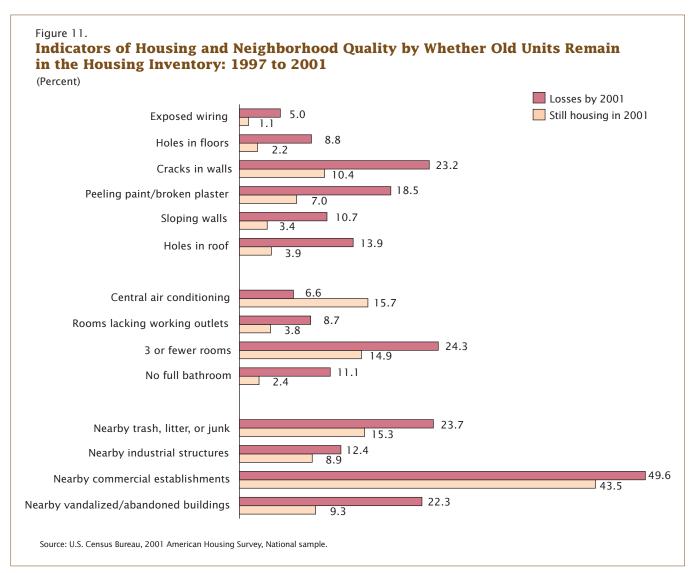

For old homes, permanent losses outnumber temporary losses (Table 16). The demolition and disaster category is the leading reason for the loss of old housing stock. About one—third of all losses (33.4 percent), and half of permanent losses (51.5 percent) fall into this category. Structural conversions and "other" temporary losses are the least common causes for losses. Statistically significant rankings for the remaining reasons are not possible due to the small number of cases involved.

Characteristics of Lost Housing

Do old structures that continue to serve as housing differ from those that are destroyed or converted to other uses? Figure 11 compares selected 1997 characteristics of housing units built before 1920 by whether the unit remains in residential use in 2001.²¹ These data show that the poorer quality units are more likely to fall out of the

housing inventory than those in better condition or with more amenities.

Also, units that were occupied in 1997 stood a much greater chance of remaining in the inventory in 2001 than those that were vacant: only 3.5 percent of the old units that were occupied in 1997 were lost by 2001, with 2.1 percent of the owner-occupied and 5.4 percent of the renter-occupied homes lost by that time (Table 17). Of the old vacant units in 1997, 16.5 percent dropped out of the housing stock, either permanently or temporarily, by 2001. However, losses among the occupied units were more often permanent

²⁰The count of structural conversions is not different from that for mergers. The number of "other" temporary losses is smaller than the count of mergers, but not different from the count of structural conversions.

²¹All comparisons are significant, except those for nearby commercial establishments and nearby industrial structures.

losses-demolitions and the like-than were the losses among vacant units (71.2 percent compared with 55.9 percent).

Structure type did not play a major role in whether a unit was a loss. Apartments in small (2 to 4 units) multiunit buildings (7.0 percent) were somewhat more likely than 1–unit, detached structures (4.4 percent) to become a loss between 1997 and 2001. The remaining comparisons among structure types do not show differences.

As home to the largest concentration of residential structures built before 1920, the Northeast might also be expected to show the highest number of losses. However, the numbers of losses between 1997 and 2001 are not significantly

different for the Northeast and the Midwest. Both the South and the West trailed in the number of old units that dropped out of use during that period.

The South experienced the highest proportional loss of old units between 1997 and 2001. During that time, 8.4 percent of the old residential units changed to other uses or were otherwise lost from the housing stock. The figures for the other three regions are not significantly different from each other—about 4 percent for each. Demolitions or disaster losses accounted for approximately the same number of losses in the South as in the Northeast even though the Northeast had about three times as many old homes in 1997 as did the South.

CONCLUSION

Although the 1940 and 2001 counts show that the number of residences built before 1920 in the housing inventory has shrunk, these unique structures are still "home" to many households across the country. An advantage of these units is that they are relatively affordable for both homeowners and renters. Lower-income home buyers may find old structures a reasonable alternative to both smaller, less expensive manufactured housing units and to larger, but more costly, new conventional units.

The drawbacks to this vintage of homes include the lack of contemporary amenities and larger maintenance requirements. Since old units are found chiefly in the Northeast and Midwest, units built

before 1920 are not available for many households seeking a home.

The long-term erosion in the inventory of old homes is basically irreversible. Demolitions and disaster losses are the current major reason old residential units fall out of the inventory, and there is no recovery from these processes. The number of old units is likely to continue to dwindle through decay and through outright elimination in order to reuse the property. However, these old houses have already weathered numerous storms in their lifetime, and many have the utility, substance, and unique character to continue as housing for many more years.

Additional detailed tables are available at www.census.gov/prod/2004pubs/h121-04-1.pdf.

SOURCE OF DATA

The data in these tables are based on the American Housing Survey (AHS). The population represented (the population universe) in the 2001 AHS include the occupied and vacant housing units in the United States. Housing in institutions (such as correctional facilities or nursing homes) or in group quarters (primarily student or

military dormitories) are not in scope. The AHS is a longitudinal survey conducted at 2-year intervals. The data in this report were collected from August through November of 2001 and represent the ninth interview at the original sample addresses. The data in these tables contain sampling error and nonsampling error. Data users who create their own estimates using data from Census Bureau tables should cite the Census Bureau as the source of the original data only. For the full technical documentation, definitions of subject characteristics and geographic definitions see www.census.gov /hhes/www/ahs.html.

ACCURACY OF THE ESTIMATES

Statistics from surveys are subject to sampling and nonsampling error. All comparisons presented in this report have taken sampling error into account and meet the U.S. Census Bureau's standards for statistical significance.

Nonsampling errors in surveys may be attributed to a variety of sources, such as how the survey was designed, how respondents interpret questions, how able and willing respondents are to provide correct answers, and how accurately the answers are coded and classified. The Census Bureau employs quality control procedures throughout the production process, including the overall design of surveys, the wording of questions, review of the work of interviewers and coders, and statistical review of reports.

The American Housing Survey employs ratio estimation, whereby sample estimates are adjusted to independent estimates of the national population by age, race, sex, and Hispanic origin. This weighting partially corrects for bias due to undercoverage, but how it affects different variables in the survey is not precisely known. Moreover, biases may also be present when people who are missed in the survey differ from those interviewed in ways other than the categories used in weighting (age, race, sex, and Hispanic origin). All of these considerations affect comparisons across different surveys or data sources.

For further information on statistical standards and the computation and use of standard errors, see www.census.gov/hhes/www/ahs.html.

⁻ Not applicable.

Source: U.S. Census Bureau, 2001 American Housing Survey, National sample.

^{...} Zero or rounds to zero.

¹Figures exclude manufactured/mobile homes.

²Does not include cooperatives or condominiums.

³Figure may not add to total, because more than one category may apply to a unit.

⁴Excludes units where primary source of water is commercial bottled water.

⁵Other causes and equipment breakdowns may not add to total, as both may be reported.

⁶Limited to single attached and multiunits.

⁷Because Hispanics may be of any race, data can overlap slightly with other groups. Most Hispanics report themselves as White, but some report themselves as Black or in other categories.

⁸May reflect a temporary situation, living off savings, or response error.

⁹Regular mortgages include all mortgages not classified as home equity or reverse.
